

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

## Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + Keep it legal Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

## **About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

## ORDNANCE OFFICE,

WASHINGTON, FEB. 13, 1845.

### Hon. WM. WILKINS, Secretary of War.

Sin: In the year 1839, this Department proposed the construction of a Ballistic Pendulum for the purpose of prosecuting, in an accurate manner, many experimental enquiries essential to the advancement of the science of gunnery, and to acquiring a knowledge of the principles which should govern, in determining the proper proportions of length and weight, in the construction of cannon, and the best mode of fabrication of gunpowder for artillery purposes, and introduced in its estimate an item for that purpose.

This measure was approved by Mr. Secretary Poinsett, and the sum asked for was appropriated, but owing to the absence of the greater part of the Officers composing the Ordnance Board, on a visit to Europe, the construction of, and experiments with, the Pendulum were not commenced until the year 1842. This duty was then assigned to Capt. Mordecai, who has, since that time, been engaged therein under the direction of this office. Having completed the construction of, and a course of experiments with, the Cannon pendulum, to which was subsequently added a Musket pendulum, for the determination of similar principles in reference to small arms and powder therefor, Capt. Mordecai has now presented his first report, shewing the nature of his experiments, so far as they have been carried, and their results. This report exhibits great skill, industry and scientific knowledge on the part of that officer, and contains a mass of facts highly important to be known generally in the service. I, therefore, submit the report for your examination, and propose, with your sanction, to cause it to be printed and distributed for general information-the expense of which may be defrayed from a balance of the appropriation for the Pendulum yet remaining.

İ۳

While on this subject I may remark that there is, in possession of this Department, much other valuable information, the knowledge of which would be of great advantage to the military service of the country, and which it is proposed to digest and prepare for publication from time to time.

I am, sir, very respectfully.

Your obedient servant,

(Signed)

G. TALCOTT, Lt. Col. Orda.

Having examined the Report of Experiments referred to in the above communication, and believing that the work is of a nature to be highly interesting and useful to the military service, I approve of its publication. The Chief of the Ordnance Department will, therefore, take measures to have the Report printed under the immediate superintendence of Capt. Mordecai.

| (Signed) | WM. WILKINS,  |

## INTRODUCTION.

In the summer of 1842, I received from the Ordnance Office instructions to erect at Washington Arsenal a ballistic pendulum, and a gun pendulum, to serve for experiments in gunnery and also for the proof of gunpowder.

The iron work for these pendulums was prepared at the West Point foundry, and it was received at the Arsenal in December, 1842, at which time the piers and sheds for the pendulums had also been completed; but, in consequence of the intervention of other duties, the erection of the pendulums was not commenced until the end of January, 1843. The adjustment of them and some preliminary trials for testing the accuracy and the stability of the work, were made during the favorable weather in the winter and spring. In the beginning of May the apparatus was reported ready for use, and a programme of the proposed experiments on gunpowder was submitted to the chief of the Ordnance Department and adopted.

In the course of the experiments, a minute journal of all the operations was carefully made, and is preserved at the Arsenal. That journal will be presented almost verbatim in this report, the principal alteration in it being that required for bringing to-

#### INTRODUCTION.

gether all the experiments of each kind, for the sake of facilitating a reference to them.

By this course, all the circumstances which have an influence on the results of the experiments will be presented in detail, so that those results may at any time be verified, and an estimate may be formed of the value of the authority from which they are derived. The candor and minuteness with which Hutton has rendered an account of his experiments have been commended by all subsequent writers on the same subject, and his example is worthy of imitation by those engaged in the like . pursuit.

The journal contains, for each day on which experiments were made, an extract from the Meteorological Register kept at the Hydrographical Office in Washington, and an abstract of these observations is appended to this report. Other causes of variation, in the results of such experiments as the present, are so much more influential than those arising from changes in the state of the atmosphere or of the weather, that no attempt is here made to correct those results for a normal meteorological condition; but this register will furnish the elements for such correction, if in the course of a long series of experiments it should be found that there are variations which may be fairly attributed to atmospheric influence. With few exceptions, the experiments have been made in favorable, pleasant weather.

When I was first charged with the direction of these experiments, I suggested to the chief of the Ordnance Department to endeavor to procure, through the legation of the United States

#### INTRODUCTION.

in France, copies of the reports which might have been made of the experiments on gunpowder at Metz, as such reports would be highly valuable for the purpose of comparing and verifying the results obtained in the experiments which we proposed to make. In pursuance of this suggestion, application was made to the War Department of France, and through the great kindness and liberality of the Minister of War, Marshal Soult, a manuscript copy of a very elaborate report of experiments on gunpowder was furnished to the Ordnance Department. That report was received in July, 1843; it embraces experiments of a kind similar to those proposed in my programme, and extends also to other points of practical importance in such investigations. Some of its conclusions will be alluded to in discussing the results of the present experiments.

I take pleasure in acknowledging my obligations to Major Symington, the commanding officer at Washington Arsenal, for the facilities extended to me in making these experiments: to several of the workmen employed at the arsenal, and especially to the master armorer, Mr. Fisher, I am also indebted for the zeal and intelligence displayed in perfecting the mechanical arrangements of the various apparatus, and in executing my designs.

PROGRAMME OF THE EXPERIMENTS.

## PART FIRST.

## 1. PROGRAMME OF THE EXPERIMENTS.

In order to establish a standard of proof by means of the ballistic pendulum, it was first necessary to compare the strength and other qualities of the various kinds of gunpowder now in service; and it was thought advisable, also, to extend the comparison to other kinds of powder, differing from these in the mode of manufacture, the proportions of the composition, the size of grain, density, &c. In the course of the experiments, other varieties of powder, not embraced in the original programme, were subjected to trial.

It was proposed to try many of these varieties of powder by the ballistic pendulum, with various charges, with both shot and shells, and to compare the indications of the strength of powder given by the pendulum with those of the common mortar eprouvette, and of the eprouvettes used in the British and French services. This comparison was subsequently extended to a trial with small arms, by means of a musket pendulum established on the same principles as the cannon pendulum.

It was further proposed to compare other physical qualities of the several kinds of powder, by ascertaining their density, relative quickness of burning, tendency to absorb moisture, &c.

The apparatus used for these several trials and comparisons are described, and the results set down, under their appropriate heads.

The natures of all the varieties of powder are exhibited in the subjoined tabular view, to which the requisite explanatory romarks are annexed.

## E EXPERIMENTS.

#### Remarks explanatory of the foregoing Table.

The figures 0, 1, 2, 3, 4, 5, 6, attached to the letters which designate the different kinds of powder, denote the several sizes of grain of each kind.

A. 0, & F. 0, are samples of very large grains of powders A & F, containing no grains which will pass through the coarsest sieve for cannon powder.

No 4 denotes musket grain; No. 5, rifle; and No. 6, sporting.

Nos. 1, 2, 3, denote three different sizes of grain obtained by sifting cannon powder with sieves corresponding with the regulation gauges for the inspection of powder; the diameters of the holes in these sieves are:

|         |   |   |   | Incn. |
|---------|---|---|---|-------|
| Maximum | - | - | - | 0.100 |
| Medium  | - | - | - | 0.085 |
| Minimum | - | - | - | 0.070 |

No. 1 denotes the size of grain between the maximum and medium sieves; No. 2, between the medium and minimum; and No. 3, that which passes through the minimum.

In the powders E, F, G, K, L, M, R, the separation of the different sizes of grain was made at the powder works; the powders A, B, C, D, were sifted at the Arsenal. The following table shows the proportions of the several sizes of grain in these powders, obtained by sifting one sample; and it also shows the proportions of the different sizes which are required by the regulation for the inspection of powder:

| Pow              | der sifted.                                  | Quantity<br>remaining                     | Beiween No. 1 & 2. Samples of cannon powder sifted, August 11th, 1843.

Of these powders, sample A alone agrees pretty nearly with the regulation; samples B and C contain too little of large grain and too much of small grain, which also is too fine, as will be seen by the number of grains in a given weight stated in a future part of the Report; sample D is nearer to the proper size of grain, but there is too much inequality in it.

Of these four kinds of powder a considerable quantity was procured for the Ordnance Department in 1837 and 1838, and they constitute the principal part of the stock now in the magazines. Nearly all the other kinds used in these experiments (except the foreign powders) were prepared expressly for this purpose.

In procuring some powder in 1837, from the powder mills at Nitre Hall, near Philadelphia, I found that, in consequence of the great density and hardness imparted to it by the press, (although incorporated by the pounding mill,) the coarse grain, or cannon powder, gave so low a range with the mortar eprouvette, (180 to 200 yards,) that it could not be received, under the regulations, although the fine grain or rifle powder, sifted from the same, gave an uncommonly high range. I

thought it would be interesting to test this powder with large charges in the cannon, and as the Nitre Hall mills were not in operation, I had similar powder prepared at Dupont's mills. This is the powder designated by the letter E, in which the hardness and density of the grain are undoubtedly carried to excess.

In contrast with this very hard grain is the powder F, which is made according to the French process, in all respects except in the kind of coal; *cylinder coal*, or coal made by the distillation of the wood, having been used instead of that burnt in pits. This powder, not being pressed or glazed, is very light and soft grained, and in these respects it presents an extreme case of an opposite nature to that offered by the powder E. The error in the kind of coal used was corrected in making the powder K, which differs from the common French war powder only in being worked 14 hours instead of 11 hours.

G. 1 is a sample of cannon powder made from the same cake as the fine canister sporting powder designated by G. 6.

H is a sample of English government powder, captured in 1813, and placed probably at that time in the magazine near Boston, belonging to the State of Massachusetts. The appearance of the powder affords satisfactory evidence of its being the kind indicated by the marks on the barrel; it is in excellent order, free from lumps and containing very little dust.

T is a sample of such powder as is commonly sold for blasting rocks; it is made of crude Calcutta saltpetre and common charcoal, and is probably incorporated by pounding in large mortars.

W is the powder used for ordinary service at Washington Arsenal, having been longer in the magazine than the other kinds. The mills where it was made being no longer in existence, the particulars of the mode of manufacture could not be accurately ascertained.

The samples of English and French government powders

were obtained directly from the War Departments of the respective countries, and the packages are carefully marked with the description and proof of the powder contained in them, as follows:

#### ENGLISH POWDER.

Cannon powder. Made of willow charcoal; stoved at Waltham Abbey, 22d September, 1838; proved 4th October, 1838; mean vibration of the gun eprouvette  $22^{\circ}.3$ ; weight of 1 cubic foot,  $54\frac{1}{2}$  lbs. (872 oz.)

Musket powder. Made of willow coal; stoved 23d March, 1839; proved 25th March, 1839; mean vibration 26°.4; weight of a cubic foot 52<sup>3</sup>/<sub>4</sub> lbs. (844 oz.)

*Rifle powder.* Made of dogwood coal; stoved 5th May, 1836; proved 9th July, 1836; mean vibration of gun eprouvette  $28^{\circ}.1$ ; weight of a cubic foot  $51\frac{1}{4}$  lbs. (820 oz.)

## FRENCH POWDER.

Cannon powder. Made at Bouchet, between the 1st April and 30th September, 1838; range with the mortar eprouvette 249 metres, (272 yds.;) gravimetric density 804.

Initial velocity, by musket pendulum, 516 metres, (1,694 feet); the proof charge being 10 grammes = 154 grains troy.

Musket powder. Made at Bouchet, between the 1st April and 30th September, 1838; range with the mortar eprouvette, 246 metres, (269 yds.;) gravimetric density 830.

Initial velocity, by musket pendulum, 508 metres, (1,667 ft.) Sporting powder, (Poudre Royale.) Made at Esquerdes in

1838. Proof by musket pendulum: charge 5 grammes, (77 grains troy;) ball 0.02562 kil., (395.4 grs.;) initial velocity 398 metres, (1,306 feet.)

The Swedish powder is a sample sent by Baron Wahrendorf, the proprietor of the cannon foundry of Aker.

The particulars of the composition and mode of manufacture of most of the powders mentioned in the foregoing table were obtained from the manufacturers themselves. The composition of the samples A, B, C, and D, has been verified or corrected, and the purity of the saltpetre tested, by an analysis made for me in the course of some comparative experiments with these powders in 1838.

None of these powders have been subjected to transportation by land for any considerable distance; they are therefore generally clean and free from dust, with the exception of the *unglazed* powders which will not bear ordinary handling or sifting without creating a good deal of dust.

They have been well preserved in good dry magazines, except the samples a and W, which were taken from the magazine at the Little Falls of the Potomac, about six miles above Washington Arsenal. This magazine is in a low, damp situation, but it cannot be said that the powder received from it has suffered any deterioration which is apparent on mere inspection.

#### 12 EXPERIMENTS WITH THE CANNON PENDULUM.

#### II. EXPERIMENTS WITH THE CANNON PENDULUM AND ITS BALLISTIC PENDULUM.

DESCRIPTION OF THE PENDULUMS.—Plate 11.

The order for the construction of these pendulums directed that they should be made on the plan of those recently erected at Metz, in France, of which a description, with drawings, had been procured by Messrs. E. J. Dupont & Co., of Delaware, and obligingly communicated to the Ordnance Department. This plan was accordingly followed, with some modifications in the details, most of which modifications had been suggested by experience in the use of the pendulums constructed at Metz.

## Conditions to be fulfilled.

The principal conditions to be fulfilled in the arrangement of these pendulums were:

1st. That the pendulum block should be capable of sustaining, without injury, the impact of balls of large calibre, moving with great velocity; as it was proposed to use in the experiments a 24-pounder gun, with a charge of  $\frac{1}{2}$  the weight of the shot, and a 32-pounder, with a charge of  $\frac{1}{4}$ , or even  $\frac{1}{3}$ .

2d. That the *core* or part of the block which receives the impact of the ball, should be susceptible of being easily and quickly renewed after each fire.

3d. That the frame of the gun pendulum should be capable of receiving guns of various calibres.

4th. That arrangements should be made in each pendulum for adjusting the height of its centre of oscillation, so as to make it coincide with that of the line of fire, in order to prevent violent shocks on the axis of motion.

5th. That the apparatus should not be liable to be affected by hygrometric changes in the atmosphere.

These conditions were fulfilled in the following manner :

#### DESCRIPTION OF THE PENDULUMS.

#### The pendulum block.

The pendulum block is of cast iron, in the form of a hollow frustrum of a cone, with a hemispherical bottom. In order to give it the requisite strength, the block is closely hooped with wrought iron over all the conical part, except in the places where it is embraced by the suspension straps; for this purpose the block was first turned, and the hoops were accurately reamed in a lathe, and then shrunk on to their places, using in this operation only heat enough to set the hoops closely to the cast iron.

In order to facilitate the adjustment of the centre of oscillation of the pendulum, by throwing the weight as far as possible from the axis of motion, the block was made thicker on the lower side than on the upper, by placing the core of the hollow part above the centre of figure, thereby bringing the centre of gravity of the block 0.5 in. below its axis. This object would have been better effected by placing the axis of the core, instead of that of the exterior of the block, in the line of fire.

The opening in the face of the block is partially closed by • an iron plate, which is held fast by bolts set in the block, and which serves to retain the sand used for filling the hollow of the block. In the centre of this plate is a circular opening 16 inches in diameter, through which the ball passes, and the point struck by the ball is marked by the hole made in a sheet of lead, (of about  $3\frac{1}{2}$  lbs. to the square foot,) which is placed over the opening in the plate and retained by a washer, or smaller iron plate, bolted to the large one; vertical and horizontal scales, drawn on the face of the small plate, serve, by means of an easy reference, to measure the position of the point struck by the centre of the ball.

## Manner of forming the core of the pendulum block.

The hemispherical bottom of the core is formed of a block of lead, which serves to counterpoise the weight of the front

i

### 14 EXPERIMENTS WITH THE CANNON PENDULUM.

part of the pendulum block, and facilitates the adjustment of the axis in a horizontal position, by bringing the centre of gravity of the system nearly in the middle point between the suspension straps; this lead forms also a sort of cushion, to receive the impact of the balls, and to prevent them from striking against the cast iron, in case they should penetrate through the sand which forms the chief part of the core of the pendulum block.

The sand which receives the impact of the balls is contained in cases made of strong leather stretched over iron frames; the frame consists of two wrought iron hoops, connected together by ribs of the same material; the diameter of each hoop is 0.75 in. less than that of the core, at the place which it is to occupy; each hoop is made in three segments, and the corresponding segments of the two hoops which form one frame, are connected together, each pair, by three ribs of square iron welded to the hoops. The leather which covers these frames is brought over the outer faces of the hoops and secured there by rivets, the sections of each hoop being connected together by the leather covering only. When the sand is compressed by the ball, the case or bag expands laterally, until it is supported by the sides of the pendulum block.

The ends of these cases are closed with boards of soft wood, about  $\frac{3}{8}$  in. thick; those which form the bottom, or smaller end of the case, rest on iron pins which are set on the inside of the smaller hoop; and those which form the head, or larger end, are kept in place by small nails driven into wooden plugs in holes on the inside of the large hoop.

In order to fill the case or bag, it is placed on its small end and the boards forming the bottom are laid down on the pins intended to support them; if there are any openings through which the sand might escape, they are closed with shavings, &c. The sand is then put in and settled with a small rammer, such

#### DESCRIPTION OF THE PENDULUMS.

as a piece of an implement staff; when nearly filled, the bag is placed on the platform of a balance, and its weight properly adjusted, after which the head is fastened in as before mentioned.

Four of these bags form a set for filling the pendulum block: the first or smallest one is 15 inches high; the second, 14 inches; the third and fourth, each, 12 inches; an interval of about 3 inches is thus left at the mouth of the block, which serves to admit any compensating weights that may be required to make up the proper charge. These weights are in the form of large rings, made of iron of different sizes, according to the weight required. The vacant space in the mouth of the block is requisite also for containing the sand displaced by the shot. A small portion of this sand escapes through the hole made by the ball in the sheet of lead on the face of the block.

The placing of the sand bags in the block, is facilitated by the use of a pair of large hooks, or tongs, attached to a tackle and fall, suspended from the roof of the pendulum shed and hanging just in front of the block; when not in use they are drawn aside, out of the way of the pendulum, and hung on a hook driven into the frame of the shed.

## Manner of suspending the pendulum block.

The block is suspended by means of four straps of wrought iron attached to a horizontal shaft of the same material.

The shaft terminates at each end in knife edges, made of hardened steel welded to the iron. These knife edges are rounded on a radius of 0.06 in.; inside of the knife edges, the shaft has cylindrical bearings which are turned with great care; the lower lines of the knife edges are in the surface of these cylinders produced, and consequently the axes of motion, at the two extremities of the shaft, are in the same right line.

#### 16 EXPERIMENTS WITH THE CANNON PENDULUM.

The suspension straps terminate, at their upper ends, in collars which are accurately bored to fit the cylindrical bearings on In the lower parts of these collars are slots, which the shaft. fit on corresponding projections on the shaft and prevent the straps from turning; the collars of the straps are also pressed firmly, by means of keys, against the shoulders of the shaft. The two inner straps, from each end of the shaft, pass to the front end of the pendulum block; the outer ones, to the rear end. The inner straps are straight, from the collars on the shaft to a point near the block where they take a direction perpendicular to the axis of the block, which they embrace between the shoulders provided for them. 'The outer straps are curved just below the shaft, so that at the distance of about 5 feet from the axis, the two straps from each end of the shaft are brought into the same plane, passing nearly through the axis of the block.

The work should be fitted together in such a manner that the line joining the centres of the two collars for the pendulum block, which are thus formed by the two pairs of straps, shall be in a plane perpendicular to the axis of the shaft at its middle point, and shall be also perpendicular to a plane passing through the axis of the shaft and the middle point of the line in question, which line coincides with the axis of the block. In the construction of the suspension frames, the direction of the vertical planes passing through the axes of the gun and of the pendulum block, was not perfectly accurate in either system; and in order to make these planes coincide, so that the line of fire should pass through the centre of the block, it was found necessary to adjust their direction, by inserting a washer between the collars of the straps on one end of each shaft, which had the effect of drawing the breech of the gun and of the block towards that end of the shaft.

The pair of straps which embrace the front part of the block

#### DESCRIPTION OF THE PENDULUMS.

approach, above and below the block, within 8 inches of each other, and are kept apart by iron transoms which terminate at each end in bolts that pass through the straps and are held by nuts on the outside. The other pair of straps come together within 2 inches, and the bolts which serve to press them against the block pass through the flattened heads of two large transverse bolts, the other ends of which are cut with a screw thread. The ends of these bolts pass through holes in the transoms of the front pair of straps, and the bolts have strong screw threads cut on their whole length, for a purpose which will be hereafter explained.

Between the pendulum block and the shaft, the two straps from each end of the shaft are firmly connected together by two pairs of flat braces, having shoulders which bear against the edges of the straps; the upper braces are bolted to the straps and they are connected together by a large cross bolt which passes through the middle of each; the lower braces are connected with the straps, and with each other, by means of cross bolts. All of these cross bolts have bevel washers against their shoulders inside, and under the nuts, outside of the braces.

## Supports of the pendulum.

The knife edges of the shaft rest in V's formed in dies of hardened steel, which are set in cast iron seats; these seats are bolted down to large cast iron plates, resting on the tops of two stone piers to which the plates are secured by long bolts let into the stone. On the upper sides of the plates there are projecting ledges between which the seats for the V's are placed, and the position of these seats is regulated by means of wedges inserted between them and the projections on the plates. The bolt holes in the seats are made of an oblong form, in order to admit of adjustment, so that the two V's of each pair shall be in

17

I

## 18 EXPERIMENTS WITH THE CANNON PENDULUM.

the same horizontal line, and that these lines, in the two pendulums, shall be parallel to each other.

The bottom parts of the V's are rounded on a radius of  $\frac{1}{1 \sqrt{5}}$ th of an inch; and the inclination of the sides is so arranged, with reference to that of the planes of the knife edges, as to allow the pendulum to vibrate through an arc of  $30^{\circ}$ .

The parallelism of the two shafts is verified by means of two plumb lines, suspended to the ends of a needle attached to each shaft in a direction perpendicular to its axis. Four other plumb lines are suspended in the axis of the gun and block, (on the front and rear of each,) and when the adjustment is perfect, these eight plumb lines should hang in the same plane.

## Measurement of the arc of vibration.

The vibration of the pendulum is measured on a brass limb, placed under the axis of the block and supported by wrought iron chairs set in stone posts. A slider, also of brass, moves on this limb, and is held at any point by the pressure of a light spring; the slider is moved by an index attached to a bar connected with the lower ends of the suspension straps. The limb is graduated in degrees and minutes, and the slider has a vernier which reads to two seconds. 'The zero of the arc is placed in the vertical plane passing through the axis of motion, and the face of the index is also in this plane when the axis of the block is horizontal, or situated in the line of fire. In order to have the means of verifying the adjustment of the limb, at any time, if necessary, two hollow centres are screwed into the under side of the shaft, near each end, for the purpose of suspending two plumb lines that shall hang in the vertical plane through the axis of motion.

## Shed for covering the pendulum.

The whole apparatus is protected from the weather by a wooden shed, which has large openings in the sides and scut-

#### DESCRIPTION OF THE PENDULUMS.

tles in the roof, to permit the escape of the smoke and to prevent injury from the blast of the gun.

## Gun pendulum.

The suspension frame, the supports, and the general arrangement of the gun pendulum, are similar to those of the ballistic pendulum, and it is therefore necessary to describe only the manner of attaching the gun to the frame.

In order to provide for mounting guns of any calibre below a 32-pounder, the diameter of the circular parts of the suspension straps is sufficiently large to admit collars of cast iron which may be adapted to the gun and made to fit on the trunnions, having shoulders to receive the straps; but the 32 and 24-pounder guns, heretofore attached to the pendulum, having been made for the purpose, the projecting pieces, to form the shoulders for the straps, were cast on the guns. In order to facilitate the adjustment of the centre of oscillation of the pendulum, and also to have a gun which shall be perfectly safe to use, with any charge up to  $\frac{1}{2}$  the weight of the shot, the 24pounder has been made on the same model as the 32-pounder, and the trunnions are omitted, as the piece is designed for use with the pendulum exclusively.

When the piece is to be changed, the gun is supported by a scaffold placed under it; the bolts and keys are then loosened, and the straps detached, after which the gun is removed, another put in its place, and the straps again driven up. In replacing the straps, it is necessary that the cross bolts of the lower set of braces, and the bolts of the transoms in the front straps, should be entered at the same time; all the other parts can be put together after the straps are in place.

## Adjustment of the centre of gravity and of the centre of oscillation.

The two systems being nearly symmetrical, with reference to the vertical planes through the axis of motion and the axis

#### 20 EXPERIMENTS WITH THE CANNON PENDULUM.

of the gun or block, the centre of gravity of each pendulum was found nearly in the intersection of these vertical planes, when the axis of the gun or block is horizontal; it is therefore necessary to provide only for correcting the deviations caused by variations in the charge of the gun, or of the block. For this purpose, adjusting weights are placed on the large screw bolts which connect the front and rear straps above and below the gun and the block; by sliding these weights backwards or forwards, the position of the vertical line containing the centre of gravity is easily adjusted. These weights effect another very important purpose, in the adjustment of the centre of oscillation of the system, so as to make it coincide with the axis of the gun or block.

The weight of the gun and block being very great, in comparison with that of the suspension frame, the centres of oscillation were found to be nearly at the proper height, and the adjustment of them was readily effected by placing weights on the lower screw bolt, which has the effect of lowering the centre of oscillation; the upper screw bolt would be made use of in the same manner, in case the centre of oscillation should be found, by any change of circumstances, to be too low. These screw bolts are flattened, or planed off, at the sides, in order to allow the weights to slide on them more readily. The weights are cylinders of various heights, having slits of the thickness of the screw bolt, to facilitate placing and removing them. The slits are lined with thick sheet iron to prevent the weight from being cut by the screw, and the height of the slit is so regulated (for convenience in calculation) as to bring the centre of gravity of the weight in the axis of the bolt on which it rests. The weights are made of lead, with about 6 per cent. of tin; they are moved on the bolt, and are also held in place when set, by means of large nuts with handles, of which there are two on each bolt. To prevent these nuts from being pressed into the

#### DESCRIPTION OF THE PENDULUMS.

weights by their reaction in the recoil of the pendulum, broad iron washers are placed between the weights and the nuts, and the front weight for each pendulum is made of a shell of cast iron  $\frac{1}{2}$  inch thick, filled with lead.

## Weight of the pendulums.

Before the frames were put together, the weights of the several parts, and also of the gun and block, were carefully determined and verified by means of different balances; and the weight of each system was thus ascertained to be as follows:

| Weight | t of the 4 straps of the gun frame  | -     | lbs.<br>481 : | 479:  | 489;;          | 4831. |

| "      | face plates and bolts for do.       | •     | 143           |       |                |       |
|        | Total ballistic pendulum            |       | 9,358         |       |                |       |

## Position of the centres of gravity of the pendulums.

The position of the centre of gravity of each system was determined by balancing the frame complete on the edge of a square steel bar, placed parallel to the axis of the shaft. The place of the centre of gravity of the gun and the block being known, that of the whole system is easily calculated.

The results of this calculation were verified by actually balancing, in a horizontal position, the whole pendulum, with the gun and block in place; and the two operations were performed at different places and by different persons:

| •                                                                                                                                                                                                                         | Gun.                    | Block.                     |

The height of the centre of gravity of each pendulum in this condition being known, it is easy to make the necessary correction for the addition of the adjusting weights, and for the weight of the core of the block. For this purpose it is sufficient to observe that the centre of gravity of the adjusting weights, being in the axis of the lower screw bolts, is, in the gun pendulum, at 215 inches from the axis of motion, and in the ballistic pendulum, at 219 in. The centre of gravity of the hemisphere of lead in the bottom of the pendulum block is in the axis of the block, or 195 in. from the axis of motion; and that of the conical part of the core is 0.66 in. above the the axis of the block, or 194.34 in. from the axis of motion.

In the gun pendulum, when adjusted for use with the 32pounder gun, a weight of 667 lbs. was placed on the lower screw bolt.

#### DESCRIPTION OF THE PENDULUMS.

Under these circumstances, the distance of the centre of gravity of the gun pendulum from the axis, is  $\frac{10,500 \times 172.9 + 667 \times 215}{11,167} = \frac{1,958,963}{11,167} = 175.41 \text{ in.}$ and that of the centre of gravity of the ballistic pendulum,  $\frac{9,358 \times 170.8 + 643 \times 195 + 975 \times 194.34 + 789 \times 219}{11,756 \text{ lbs.}} = \frac{2,084,162.5}{11.756} = 177.29 \text{ in.}$ 

11,756 The results of these calculations and measurements may be at any time verified, and in case of a change in the pendulums, they may be corrected, by practically ascertaining the moment of the system, *i. e.* the product of the weight into the distance of its centre of gravity from the axis of motion; and this moment is a factor which enters into the formula for the computation of the initial velocity of the ball. To ascertain the moment of the pendulum without dismounting it, it is sufficient to determine by trial the weight which, acting at a given distance from the axis, will sustain the system, out of a vertical position, at such an angle that the direction in which this weight acts shall be perpendicular to the line drawn from the centre of the axis of motion to the centre of gravity of the system. If *a* be the angle which this latter line then makes with the vertical; w the weight which balances the system, and d the distance at which it acts from the centre of motion, then will the moment of the pendulum be:

$$\frac{w d}{\sin a} = pg$$

# Position of the centre of oscillation.

The lengths of pendulums being to each other as the squares of the times of ibration, or vinversely as the squares of the number of vibrations in a given time, the distance of the centre of oscillation from the axis of motion is determined by observing the number of vibrations made by the pendulum in any

given time, or the number of seconds required for a given number of vibrations of the pendulum.

In the present instance this was determined by observing, with a chronometer which beats half seconds, the time required for 500 vibrations of the pendulum, commencing in an arc of about one degree and a half. The length of the seconds pendulum at Washington, (latitude  $38^{\circ} 53' 23''$ ,) being 39.1 in., the distance of the centre of oscillation of a pendulum vibrating 500 times in *n* seconds, will be

$$L = \frac{n^2 \times 39.1}{500^2}$$

and in order that L shall be equal to 195 in., or that the centre of oscillation shall be in the line of fire of the pendulum gun, n must be = 1,116.5 seconds.

In the gun pendulum, this adjustment of the time of vibration is effected by placing an additional weight of 667 lbs. on the lower screw bolt, as above mentioned in ascertaining the position of the centre of gravity. In the ballistic pendulum, when ready for use and loaded as above stated, the time required for 500 vibrations is 1,116 seconds, and the position of the centre of oscillation is at 194.8 in. from the axis.

When the position o' of the centre of oscillation is accurately ascertained, for any given condition of the system, the additional weight W, requisite to bring that centre into any other position, o may be computed very nearly by the formula

$$W = \frac{p g (o - o')}{d (d - o)}$$

pg being the act al moment of the pendulum, and d the distance of the additional weight from the axis of motion.

In consequence of the lightness of the frames, in proportion to the whole weight of the pendulums, they are found to possess a great degree of sensibility; when vibrating in an arc of  $14^{\circ}$ , they lose about 36'' in one vibration; in an arc of  $4^{\circ}$ ,

#### DESCRIPTION OF THE PENDULUMS.

about 25". When set in motion in an arc of 12°, the gun pendulum continued to vibrate about 24 hours, and the pendulum block (empty) about 30 hours.

# Distance between the pendulums.

In order to ascertain the least distance at which the pendulum could be placed from the gun without being too much affected by the blast, a rude experiment was made by suspending a 24pounder gun to a rod 20 feet long, and attaching to the muzzle of the gun a disc 34 inches in diameter. Against this disc, blank cartridges were fired from a 32-pounder gun; a screen, with a hole of 12 inches diameter, being interposed between the gun and the disc. In this manner it was ascertained that, at the distance of 48 feet from the muzzle of the gun, the pendulum would be but slightly affected by the blast, and it was therefore determined to place the axes of the two pendulums 55 feet apart.

In order to intercept the blast of the gun as much as possible, a fixed screen of 2 in. oak plank is placed 17 feet in front of the face of the pendulum block, having a hole in it 12 inches diameter for the passage of the ball. The protection afforded by this screen is such, that with a blank charge of  $\frac{1}{3}$ from the 32-pounder gun, the vibration of the pendulum block does not exceed 45"; which vibration, if produced by the impact of a ball, would require a velocity of only 0.85 ft.

The penetration of the 32-pounder balls, in the sand of the pendulum block, is about 4 feet. It is found that, in consequence of the great and sudden compression of the sand, produced by balls moving with great velocities, the penetration does not increase with the charge; but the pressure against the sides and bottom of the block is necessarily greater with higher charges, and under these circumstances, the mass of lead in the bottom of the block is so much compressed and

battered as to make it inexpedient to fire with high charges  $(\frac{1}{4} \text{ or } \frac{1}{3})$  from the 32-pounder gun, without filling the block with some material affording a greater resistance than sand.

#### SERVICE OF THE PENDULUMS.

Open all the doors and windows of the sheds, and fasten them back; observe whether the nuts of the several connecting bolts are screwed up tight, and whether the shoulders of the knife edges swing clear of the seats. Wipe out the V's and oil them with a small quantity of clear oil.

# 1st. The ballistic pendulum.

Load the pendulum block with the sand bags, driving them in with handspikes, so as to make them bear on each other; put on the face plates with the sheet of lead previously adjusted between them.

Adjust, if requisite, the position of the centre of oscillation of the pendulum, and in order to maintain this adjustment, let the sand bags be always filled to the same weight as at first. If this cannot be done, make up the correct total weight by placing some of the iron rings within the mouth of the block.

Wipe the graduated arc and move the adjusting weights on the lower screw bolt, so that, the pendulum being at rest, its index shall be in contact with the slider when the latter stands at *zero*; in this position the axis of the block is horizontal : see that the nuts on the screw bolts are set firmly against the adjusting weights.

After the gun is fired, two men stop the vibrations of the pendulum block, checking them gradually with the hand, (or with a rope thrown over the breech,) and taking care not to displace the slider on the arc.

Note the arc of vibration.

Bring up a truck cart under the mouth of the block to re-

#### DESCRIPTION OF THE PENDULUMS.

ceive the sand when it is withdrawn. Take off the face plates and ascertain the position of the point struck by the centre of the ball, by referring the extremities of the vertical diameter of the hole made by the ball to the graduated scales on the outer plate. If necessary, note also the lateral deviation of the shot. Withdraw the sand and the ball, &c.; clean out the block with the rake and brush provided for the purpose, and take the sand, with the bags, to the filling shed.

# 2nd. The gun pendulum.

'The centre of oscillation is supposed to have been properly adjusted.

Wipe out the gun, insert the cartridge, push it home with the rammer, and measure the length which it occupies in the bore by means of the graduated brass scale set in the rammer staff for that purpose; insert the shot, ram it home and measure in the same manner the height of the whole charge; prick the cartridge, and prime with a tube having a short piece of quick match inserted in the cup, in order to give time for withdrawing the linstock before the gun recoils. A quill or paper tube is preferable for priming with, as the metal tubes are driven with considerable force against the sides, or the roof, of the shed.

Wipe the graduated arc and adjust the index of the pendulum as before, taking care that the nuts on the screw bolt are set firmly against the adjusting weights.

Before giving the order to fire, be sure that both pendulums are at rest and in their true positions.

After the discharge, note the arc of recoil.

Two men stop the vibrations of the pendulum by throwing a rope over the breech of the gun against the suspension frame; in this manner they are less apt to twist the frame than when acting directly with the hands against the gun. Clean out the gun and prepare for another charge. During the firings the pendulums  $\frac{1}{4}$ 

should be carefully observed to see if any derangement occurs in the position of the shafts in their V's, or in the stability of the frames, the tightness of the nuts, &c.

Nine men are required for the regular service of the pendulums, viz: two at the gun, who also have time to assist in charging the pendulum block; three at the pendulum block; and four to fill and wheel the sand bags. With this number of men the 32-pounder gun can be fired at the rate of about 4 rounds an hour.

#### Position of the pendulums.

The place occupied by the pendulums, and the direction of the line of fire, are shown in the sketch of the Arsenal grounds represented in PLATE 1.

The axis of the gun is situated 17.06 feet above the surface of the wharf which is crossed by the line of fire, and on which a target was erected for some preliminary experiments. The surface of the wharf is about 8 feet above the level of ordinary low water in the river.

# FORMULÆ FOR COMPUTING THE VELOCITY OF THE BALL FROM THE RECOIL OF THE PENDULUMS.

# 1. By the ballistic pendulum.

The formula for the velocity with which the ball strikes the pendulum block is:

$$v = \frac{2 \sin \frac{1}{2} A \sqrt{(pgo + bi^2)(pg + bi)G}}{bi}$$

where v is the required velocity of the ball in a second;

- p the weight of the pendulum;
- g the distance of its centre of gravity
- from the axis of o the distance of its centre of oscillation
- motion; i the distance of the point of impact
- b the weight of the ball;

#### FORMULÆ FOR THE VELOCITY OF THE BALL.

A the angle of first vibration of the pendulum;

G the measure of the force of gravity, = 32.155 ft., at Washington.

'The demonstration of the correctness of this formula is given by Hutton in his Mathematical Tracts, (34th Tract,) and is to be found also in many of the elementary works on Mechanics. It is here repeated for the satisfaction of those who may not have such works at hand for reference.

The weight of the ball being represented by b, its mass or quantity of matter is  $\frac{b}{G}$  and its quantity of motion before the impact is  $\frac{bv}{G}$ .

The moment of this quantity of motion, with reference to the axis of suspension of the pendulum, is  $\frac{b \ v \ i}{G}$ .

The quantity of motion communicated to an element dm of the mass of the pendulum, situated at a distance r from the axis of motion, is Vr dm, V being the angular velocity of the pendulum after the impact. The moment of this quantity of motion with reference to the axis is  $Vr^2 dm$ , and the sum of all such moments, or the moment of the pendulum, is  $V \int r^2 dm$ , which is  $= \frac{Vp g o}{G}$ , since  $o = \frac{G \int r^2 dm}{p g}$ .

After the impact, the ball partakes of the motion of the pendulum; its quantity of motion is therefore  $\frac{b V i}{G}$ , and its moment with reference to the axis is  $\frac{b V i^3}{G}$ . Hence the sum of the moments after the impact is  $\frac{V}{G}(pg o+b i^3)$ , and this being equal to the moment of the quantity of motion of the ball before the impact, we have:

$$\frac{bvi}{G} = \frac{V(pgo+bi^2)}{G};$$

.

consequently  $V = \frac{b v i}{p g o + b i^2}$  (1)

Again, in the recoil of the pendulum, its centre of gravity rises through the height of the versed sine of the angle of vibration, which is represented by

 $g - g \cos A = g (1 - \cos A) = 2 g \sin^2 \frac{1}{2} A;$ also, the ball at the distance *i* from the axis rises through the height  $i - i \cos A = 2i \sin^2 \frac{1}{2} A$ . Hence the quantity of action exerted by the force of gravity on the pendulum and the ball united, during the recoil, is

$$2\sin^{2}\frac{1}{2}A\frac{(pg+bi)G}{G}=2\sin^{2}\frac{1}{2}A(pg+bi);$$

but the living force of the system is  $\frac{V^2(p g o + b i^2)}{G}$ , and this

force being double the quantity of action, we have:

$$\frac{(p g o + b i^2)}{G} = 4 \sin^2 \frac{1}{2} A (p g + b i);$$

whence,  $v = 2 \sin \frac{1}{2} A \sqrt{\frac{(p g + b i) G}{p g o + b i^2}}$ .

Substituting this value for V in the equation (1) it becomes:

$$\frac{b \ v \ i}{p \ g \ o + b \ i^2} = 2 \ \text{sin.} \ \frac{1}{2} A \sqrt{\frac{(p \ g + b \ i) \ G}{p \ g \ o + b \ i^2}}.$$
  
Therefore,  $v = 2 \ \text{sin.} \ \frac{1}{2} A \frac{\sqrt{(p \ g o + b \ i^2)} (p \ g + b \ i) \ G}{b \ i}$ , as above.

In our pendulums the axis of the gun and that of the pendulum block are adjusted on the same horizontal line, when the pendulums are at rest; therefore the ball strikes very near to the axis of the block, and in order to prevent any shock on the axis of suspension, the centre of oscillation of the system is made to coincide also very nearly with the axis of the pendulum block, and this adjustment is maintained by renewing the core of the block and restoring the pendulum after each shot to

#### FORMULÆ FOR THE VELOCITY OF THE BALL. 31

its original condition; hence the values of o and i in the above formula are very nearly equal, and the quantity p g being very great in comparison with b i, no sensible error will be caused by assuming i = o in the first term under the radical sign; the formula then becomes

$$v = 2 \sin \frac{1}{2} A \frac{(pg+bi)\sqrt{Go}}{bi}$$

Moreover, in practice with balls of the same kind and calibre, the variations in the value of b are confined within narrow limits. On this account, and in consideration of the great inequality between the terms p g and b i, we may, in the case just mentioned, assign to b i, in the numerator of the above expression, a constant value equal to the mean weight of the balls multiplied by the mean distances of the points struck from the axis of suspension. By this assumption the whole term  $(pg+bi)\sqrt{Go}$  becomes constant for one set of experiments, and the formula is perfectly adapted to logarithmic computation.

In making the calculations of the velocity for a case of extreme variation in the value of b *i*, it was found that the error produced by the above transformation of the formula, and by assuming a constant mean value for p g + b i, did not exceed  $\frac{1}{10}$  ths of a foot, in a velocity of 1,350 feet; and in ordinary cases the error is so small that it may safely be disregarded.

Since 2 sin.  $\frac{1}{2}A =$  chord of A, it is obvious from the formula, that, all other circumstances being equal, the velocity of the ball is proportional to the chord of the arc of vibration of the pendulum.

# 2. Computation of the velocity of the ball by the recoil of the gun pendulum.

For the formula for this purpose, I am indebted to the Report of experiments on gunpowder at Metz, heretofore mentioned. The formula is:

$$v' = rac{2 \sin \frac{1}{2} A' \frac{p' g' \sqrt{G o'} - c N}{i'}}{b' rac{D^2}{d^2} + rac{c'}{2}}; \text{ in which}$$

v' is the required initial velocity of the ball;

p' the weight of the gun pendulum;

o' the distance of its centre of oscillation from the axis of it the distance of the rest 
i' the distance of the axis of the gun

A' the angle of vibration of the pendulum;

b' the weight of the ball and wad;

D the diameter of the bore of the gun;

d the diameter of the ball;

c the weight of the charge of powder;

c' the weight of the cartridge, including the bag;

G the force of gravity = 32.155 ft.;

N a constant factor, of the same kind as g', G, &c., to be determined by experiment.

This formula may be deduced thus:

Denoting by V' the angular velocity of the gun pendulum, the moment of its quantity of motion is, as in the ballistic pendulum,  $\frac{V' p' g' o'}{G}$ ; also, the quantity of action of gravity, during the recoil of the pendulum, is =  $2 \sin^2 \frac{1}{2} A' \times p' g'$ , and the living force is  $V'^2 \frac{p' g' o'}{G} = 4 \sin^2 \frac{1}{2} A' \times p' g';$  $V' = 2 \sin \frac{1}{2} A' \sqrt{\frac{G}{c'}}.$ therefore,

#### FORMULÆ FOR THE VELOCITY OF THE BALL. 33

Substituting this value of V' in the expression for the moment of the quantity of motion of the pendulum, it becomes

$$2\sin.\frac{1}{2}A'p'g'\sqrt{\frac{o'}{G}}$$

As the ball and wad together leave the muzzle of the gun with the velocity v', their quantity of motion is  $\frac{b'v'}{G}$ ; but the expansive force of the fired gunpowder, which produces this quantity of motion, may be considered as acting on a surface equal to the area of a great circle of the ball, whilst it reacts on the gun pendulum (so far as respects its recoil) on a surface equal to that of the cross section of the bore. Its action on the pendulum will therefore be greater than that on the ball, in proportion as the area of the bore is greater than that of the ball, or in other words, in the proportion of the square of the diameter of the bore to the square of the diameter of the ball. The quantity of motion of the pendulum from this cause will therefore be  $\frac{b'v'}{G} \times \frac{D^2}{d^2}$ , and its moment with reference to the axis of

suspension is  $\frac{b'v'\,i'}{G} \times \frac{D^2}{d^2}$ .

Again, on the supposition that all the gaseous fluid produced by the inflammation of the charge of powder occupies the space in the bore behind the ball, we may assume, with Hutton, (Problem 19; 37th Tract,) that the mean velocity of the fluid at the moment that the ball leaves the gun is half that of the ball, or  $\frac{1}{2}v'$ ; and on the hypothesis that the charge is not too great to become wholly inflamed in the bore of the gun, the weight of the elastic gas is the same as that of the charge. The greater part of the cartridge bag being also expelled from the gun, I have supposed one-half of it to partake of the velocity of the ball, or the whole of it to move with half the velocity of the ball, and its weight is therefore included with that of

the charge of powder in the quantity c'. The quantity of motion of the inflamed powder is therefore represented by  $\frac{1}{2}v'\frac{c'}{G}$ , and its moment, with reference to the axis of suspension, is  $\frac{1}{2}v'i'\frac{c'}{G}$ . Moreover, after the ball has left the gun, this elastic fluid continues to expand, and, in consequence of the resistance of the air, to react on the pendulum and increase its recoil. It is difficult to assign a value for the quantity of motion produced by this cause, but it may be considered proportional to the quantity of powder in the charge, and it may therefore be approximately represented by the factor  $\frac{c N}{G}$ ; N being a constant linear quantity representing the velocity communicated to the pendulum by a unit of the charge c. The moment of the quantity of motion produced by this action of the charge is therefore  $\frac{c Ni'}{G}$ , the resultant of all of these forces being supposed to coincide with the axis of the gun.

The sum of all the moments resulting from the action of the charge is therefore

$$\frac{b'v'i'}{G} \cdot \frac{D^2}{d^2} + \frac{1}{2}v'i'\frac{c'}{G} + \frac{c Ni'}{G} = 2\sin \frac{1}{2}A'p'g'\sqrt{\frac{o'}{G}};$$
  
the second member of the equation being the moment of the pendulum before obtained from its recoil.

Hence,  $v = \frac{2 \sin \frac{1}{2} A' \frac{p' g' \sqrt{Go'} - c N}{i'}}{b' \frac{D^2}{d^2} + \frac{c'}{2}}$  as above stated.

There are obvious causes of error and uncertainty which may prevent the results of this calculation of the velocity from coinciding in all cases with those obtained by means of the tic pendulum, even after allowance is made for the loss of re-

i

#### FORMULÆ FOR THE VELOCITY OF THE BALL. 35

locity occasioned by the resistance of the air whilst the ball is passing from the gun to the pendulum block. The principal one of these causes is the uncertainty of the value  $\frac{1}{2}v'$ , assumed for the mean velocity of the inflamed gunpowder in the bore of the gun. It is certain also that a considerable portion of the elastic fluid escapes through the windage of the ball, and therefore the mass of fluid behind the ball is less than that of the charge of powder; but this loss of fluid is in some measure compensated by the greater velocity of the part which passes The effect now under consideration must likewise by the ball. be modified by the quality of the gunpowder and the quantity of the charge, even within the usual limits of practice, and these circumstances probably exert a still greater influence on the value of the quantity N in the term c N. In the French Report, from which the formula was obtained, the value of 420 metres (or 1,400 feet) is assigned to N, but I have found that the results of my experiments with the 32-pounder and 24pounder guns, are more accurately represented by giving to Na mean value of 1,600 ft., and it is with this value that the formula has been used in the calculations of those experiments. It will be seen hereafter that the same value of N does not appear to apply equally well to the computation of the velocities of balls of very small calibre, and this result might have been anticipated; for the intensity of the heat, and consequently the elastic force of the fluid, generated by the combustion of the charge, probably increase in a greater proportion than the direct ratio of the quantity of powder, and the value of N must therefore vary with the charge of powder, and also with the length and calibre of the gun and the density of the ball. However, as in ordinary practice with the cannon pendulum, the variations in the value of N cannot be great, and as the quantity c Nis much smaller in value than the other term in the numerator of the formula for the velocity, no considerable error arises from 5

assigning to that co-efficient a constant mean value, as above stated. Accordingly it will be seen, that there is, in most cases, a remarkable coincidence in the velocities of the ball as indicated by the two pendulums.

In order to facilitate the verification (and perhaps the improvement) of the accuracy of this formula, I have given in each experiment, under the head of *Moment of the gun pendulum*, the value of the term

$$2 \sin \frac{1}{2} A' \frac{p' g' \sqrt{Go'}}{i'} = 2 \sin \frac{1}{2} A' p' g' \sqrt{\frac{G}{i'}};$$

since, by the adjustment of the centre of oscillation in the axis of the gun, o' = i'. We must not, however, regard this quantity as a measure of the relative force of recoil, without taking into consideration the weight and windage of the ball, as well as the weight of the charge of powder.

With regard to the measurement of the angles of vibration of the pendulums, it may here be remarked that, in conformity with the practice of Hutton and others who have conducted similar experiments, I denote by A and A' the arcs of vibration indicated by the position of the slider on the graduated limb of the instrument, although strictly speaking these angles would seem to require correction; for the ball lying in the gun in rear of the vertical plane passing through the axis of suspension of the gun pendulum, and being deposited, after the discharge, in a similar position with regard to the vertical plane through the axis of the ballistic pendulum, it follows that the recoil of the former pendulum is accelerated and that of the latter retarded, in consequence of the change in the place of the ball, and that the observed angle of vibration should therefore be diminished in the former case and increased in the latter, in order to obtain the true arc of recoil. This correction would, however, be very inconsiderable, and it is also difficult to note with accuracy, in consequence of a slight movement of the adjusting weights

#### MANNER OF LOADING THE GUN.

on the pendulums, which it is almost impossible to prevent, and which alone often produces a greater change in the position of the centre of gravity of the system than that caused by the displacement of the ball.

This source of error is pointed out by M. Maguin in his notice of the pendulums constructed at Esquerdes.\*

#### MANNER OF LOADING THE GUN.

# Of the balls.

The shot and shells used in these experiments were selected in the first place by means of the large shot gauge of the calibre, and an intermediate gauge between that and the small gauge; that is to say, the diameters of the balls were:

For the 32-pounder gun, between 6.235 in. and 6.27 in.; and for the 24-pounder gun, between 5.66 in. and 5.70 in.

The exact diameter of each ball was determined by means of other intermediate gauges differing so little from each other as to make the possible error of measurement very small.

It was intended to use no shot of less weight than the nominal calibre of the gun, but in selecting those of a suitable diameter it became necessary to make use of a few that were under that weight.

With the exception of some of the first 32-pounder shot, those used in the experiments were hammered shot, sufficiently smooth and nearly spherical. Each shot was floated in mer-

<sup>\*</sup>In the manuscript copy of the French Report from which I derived the formula for the velocity of the ball by the recoil of the gun pendulum, there occurred an error of the transcriber, for the detection of which and also for the investigation of the formula itself, I am indebted to my friend Professor Ed. H. Courtenay, of the University of Virginia, a graduate of the U. S. Military Academy.

cury, and the upper extremity of the axis passing through its centre of gravity was marked with a centre punch. This point was determined by suspending over the ball a plummet, at the bottom part of which is a horizontal disk; the under surface of this disk being covered with paint, its point of contact with the ball when at rest in the mercury is easily marked. For the sake of brevity, the axis of the ball which passes through the centre of gravity will be designated as the *principal axis*.

# Of the wads.

The wads ordinarily used in the experiments are grommets, or rings formed of a single strand of packing yarn, about 1 in. thick, such as is used for the packing of pistons in machinery; this yarn is soft and very slightly twisted. The diameter of the grommet is a little less than that of the ball, to which it is attached by four leather straps about § in. wide, each pair crossing the other at right angles and being tied on the ball with twine strings; the grommet has also a cross of twine to assist in placing it and to preserve its form. The thickness of the leather straps is nearly equal to half the windage of the ball. The average weight of a grommet with straps is, for the 32-pounder ball, 0.1 lb.; for the 24-pounder, 0.08 lb. They were made as light as possible, being intended only to retain the ball in its proper position in the gun and to prevent it from rolling forward.

The grommet is placed on the lighter hemisphere of the ball, in a direction perpendicular to its principal axis.

# Of the cartridges.

The cartridge bags are made of closely woven twilled woollon stuff; they are cut with a circular bottom like those for field service, and are sewed on a cylindrical former of the regulation

#### MANNER OF LOADING THE GUN.

size, the diameter of the former being for the 32-pounder gun 5.9 in., and for the 24-pounder 5.35 in.

The charge of powder was settled in the usual manner in the bag, which was then tied down close to the powder, and the superfluous part cut off to a uniform length. The weight of the cartridge was then again ascertained by weighing together several (3 or 4) of those of the same kind. The accuracy of these weighings is demonstrated by the regularity in the excess of the weight of the cartridge over that of the powder, and even by the apparent anomalies in the weights of cartridges containing the same quantity of powders of different densities. In some cases the variations in the weights of similar cartridges are due to differences in the thickness of the material, which being procured at different times, was not perfectly uniform in quality.

The cartridges were generally filled on the day on which they were used, or on the day before, and they were kept in budge barrels, in the magazine or in the laboratory, until required for use.

The balance with which the balls and cartridges are weighed is a small French platform balance, (of the capacity of 100 lbs.,) in which the proportion of the weight on the platform to that in the scale pan is 10 to 1. A set of weights consisting of pounds and decimal parts of a pound, down to  $_{15}^{1}_{55}_{55}$  lb., was used for this balance, and the results are expressed accordingly in decimals, instead of being given in the usual divisions of the pound. This arrangement facilitates both the operation of weighing and the calculations.

# Of the manner of loading.

The cartridge being inserted, it is pressed firmly with the rammer against the bottom of the bore, and its height is measured by means of the graduation on the rammer staff. The ball is

then placed with one of the leather straps resting on the lower side of the bore, the grommet outside, so that the heavier hemisphere of the ball is next to the powder. The leather straps are designed not only to retain the grommet, but also to support the ball nearly in the centre of the bore, so that its principal axis may coincide with the axis of the gun. It was hoped by this arrangement to remove one cause of irregularity in the motion of the ball as it passes out of the gun, and from the accuracy of direction of the shot and the smoothness of the bore, after firing a considerable number of rounds, there is reason to believe that the object was in a great measure accomplished.

In order to prevent the ball from being detached from the grommet, it was found necessary to push it to its place with the end of the rammer staff, which, acting below the centre of gravity of the ball, causes it to slide on the bottom of the bore instead of rolling; the rammer being then turned, the height of the whole charge is measured. The difference between the height of the cartridge and that of the whole charge is less than the diameter of the ball, because the centre of the ball lies above the neck of the cartridge, and consequently the bottom of the ball passes beyond the tie of the cartridge and rests against the powder.

After the discharge the gun is cleaned with a cylindrical brush made of stiff bristles, and then wiped out with a common woollen sponge. The gun is washed after each series of rounds with the same powder, (generally after 3 rounds,) and is then wiped with a dry sponge.

#### NOTE.

Note.—I may here mention some circumstances observed on the impact of the ball against the face of the pendulum block:

1. The lead displaced by the ball in passing through the sheet of lead on the face of the block, is not all carried before the ball into the core of the block; a very considerable part of it is expelled laterally in the direction, as it were, of the surface of a cone whose apex is the centre of the hole made by the ball. The fragments thus expelled are traced very distinctly on the inner faces of the stone piers and on the floor and sides of the shed which covers the pendulum.

2. The hole made by the ball in the sheet of lead is considerably larger than the ball, being with the 32-pounder ball about 6.7 in. in diameter, and with the 24-pounder about 6 in. These are well known effects of the penetration of cannon balls in solid substances.

3. An observer placed in such a position as to see the face of the block unobscured by the smoke of the gun, perceives, at the moment of impact, a circle of *reddish white flame* surrounding the hole made by the ball. Having observed the same effect to be produced in firing through a sheet of lead placed in a frame, in the open air, at 50 feet from the muzzle of a 24-pounder gun, I have supposed that this flame may be produced by the combustion of minute particles of iron and lead ignited by friction. The edges of the hole in the sheet lead have a smooth surface, which may, however, be an entirely mechanical effect of the passage of the ball through the lead.

4. In firing a 32-pounder ball into the pendulum block with a charge of 8 lbs., the sand immediately before the ball was compressed into a solid mass, forming an imperfect sandstone sufficiently firm to bear handling. A specimen is still preserved in that state after a lapse of more than eighteen months. This sand, when tested with an acid, was found perfectly free from any calcareous cement.

# JOURNAL.

# March 29th, 1843.

The gun pendulum, with the 32-pounder gun mounted, was to-day adjusted with sufficient accuracy to permit of making some preliminary firings for the purpose of testing the stability of the apparatus and the accuracy of direction of the shot.

The 32-pounder pendulum gun is of cast iron, made on the same model as the ordinary sea-coast gun, except in having (as before mentioned) shoulders for the suspension straps cast on it.

| The length of bore is | - | • | - | 107.6 inches. |
|-----------------------|---|---|---|---------------|
| Mean diameter of bore | - | • | • | 6.43 "        |
| Diameter of the vent  | - | • | - | 0.175 "       |

The pendulum block not being yet suspended, a frame was placed in the centre of the pendulum house, having attached to it a sheet of lead on which were traced vertical and horizontal lines intersecting each other in the prolongation of the line which ought to coincide with the axis of the gun. Three blank charges of  $\frac{1}{8}$ ,  $\frac{1}{4}$  and  $\frac{1}{3}$  the weight of the shot were fired, and then two charges of  $\frac{1}{8}$  with balls.

The pendulum frame appeared to have sufficient strength and stiffness, no straining or loosening of the bolts being perceptible; but the gun turned in its collars about 0.5 in. to the left, (measured on the outside of the collars,) in consequence of the straps not being fitted perfectly square to the shoulders against which they rested; some of the boards of the covering shed were started by the concussion.

The first ball passed through the sheet of lead 0.75 in. and the second 0.5 in. to the right of the centre, thus confirming the indications of an error in the direction of the axis of the gun with reference to that of the shaft of the pendulum. The lead was about 0.08 in. thick, or 4 lbs. to the foot, which was

# WITH THE 32-POUNDER GUN PENDULUM.

too thick for the purpose, the fiagments being driven in some instances through the sides of the shed, although these are of  $1\frac{1}{4}$ -inch yellow pine boards.

# March 31st, 1843.

After several ineffectual attempts to correct the direction of the axis of the gun, by twisting the straps of the suspension frame, the object was effected with ease and accuracy by inserting a washer between the collars of the straps at the right end of the shaft, which has the effect of shortening the outer strap and drawing the breech of the gun towards that end.

# April 7th to 17th, 1843.

The position of the gun pendulum furnishing a favorable opportunity of comparing the actual ranges of balls projected with different velocities, with the results obtained by computation from the formulæ for the trajectory at low angles, it was thought expedient to combine this object with that of fully testing the strength of the apparatus, before erecting the ballistic pendulum.

In order to determine the co-ordinates of one point in the trajectory, a target of white pine boards, one inch thick, was erected on the wharf which is crossed by the line of fire of the gun.—(See PLATE 1.) The true direction of the axis of the gun being marked on this target, and its height above the wharf being known, the position of the point struck was readily determined; the target was 1,098 feet from the muzzle of the gun. To obtain another point in the trajectory, a base line was established, as shown in the plate, and an observer stationed at the lower extremity of this base, ascertained with a theodolite the angle with the base, which was made by a line drawn to the first graze of the ball on the water; this could be observed by means of the column of spray thrown up by the ball. The

angle at the other end of the base, made by the line of fire, was corrected by means of the lateral deviation of the ball measured on the target at the wharf, the direction of the ball being supposed to remain nearly the same until it struck the water. The height of the tide was noted at intervals during the experiments.

The grommet wads used for these experiments were made of three turns of packing yarn, and were consequently heavier than those generally used. It was intended to place them next to the powder, and they were therefore attached to the heavier side of the ball; but when the gun became a little foul, the grommet was caught under the ball, and it was found necessary to facilitate the loading by placing the grommet outside, so that after the fourth round the ball was inserted with the lighter hemisphere next the powder. The straps which held the grommets were in this case cemented to the ball and could not conveniently be removed.

It did not occur to me to make use of these experiments (as was subsequently done) for verifying Lombard's method of determining the initial velocity of a ball by means of two points. of the trajectory, one of them being near the gun. The direction of the ball in passing through the house for the pendulum block was therefore observed only to ascertain that it was nearly accurate, and the deviations from the axis were not particularly noted.

The tendency of the gun to turn in its collars was prevented by filling up with strips of sheet iron the openings between the collars and the shoulders on the gun. 'The suspension frame was fully proved in these trials to possess the requisite strength and stiffness.

Sheet brass had been used for lining the slits in the adjusting weights, by which they were slipped on the screw bolt, but it was found necessary, in consequence of the lead and brass be-

# WITH THE 32-POUNDER GUN PENDULUM.

coming upset by the inertia of the weight, to substitute a stouter lining of sheet iron.

The shed over the gun pendulum was somewhat injured by the concussion, and it became necessary to strengthen it by bolting iron straps on the outside, through the timbers of the frame, in several places. Additional windows were also opened in the right and left sides of the shed.

The adjusting weight on the lower screw bolt of the gun frame during these first experiments, was 502 lbs.; and it was found that 500 vibrations of the pendulum were made in 1,114 seconds, which gives 194.18 in. for the distance of the centre of oscillation from the axis of suspension.

With the hope of correcting the anomalies observed in the experiments of the 7th, some of them were repeated on the 17th. The results of both days' work are presented in the following table.

In the intervening ten days the suspension frame for the pendulum block had been put together and raised to its place, but without attaching the block to it. 'The balls were therefore fired through the collars of the suspension straps, where their direction was marked by their passage through sheets of lead; but in consequence of the lead being too thin,  $(1\frac{3}{4})$  lbs. to the square foot,) the hole made by the ball was not well defined.

In the experiments on the 17th, a self-registering thermometer was inserted in the bore of the gun, about 5 in. from the bottom, before and after the discharge; but the variations of temperature were found to be altogether inconsiderable, the thermometer standing at about  $77^{\circ}$  after the first discharge.

The balls were strapped with grommets, and the heavier part placed next to the powder.

.

# April 21st, 1843.

The pendulum block having been attached to its suspension frame, the requisite adjustments in its position with reference to its own axis of suspension and to that of the gun pendulum, were completed. In order to place the axis of the block perpendicular to that of the shaft of the frame, it was found necessary to introduce a washer between the collars of the straps at one end of the shaft, as in the gun pendulum.

A final adjustment of the centre of oscillation of the gun pendulum was made by placing, on the lower screw bolt, weights amounting to 719 lbs., when by two comparisons with the chronometer, of 500 vibrations of the pendulum, it was found that 1,000 oscillations were made in 2,233 seconds, giving 194.964 in. (say 195 in.) for the distance of the centre of oscillation from the axis of suspension.

# April 22nd, 1843.

The first trial of the pendulum block was made to-day. For this purpose the core of the block was filled with coarse sand and gravel, kept in place by a circular board in the mouth of the block. The weight of this core was known, and certain supplementary weights were placed on the lower screw bolt of the frame, so as to bring the centre of oscillation nearly in the axis of the block, being at 194.27 in. from the axis of suspension. The charge of powder was 4 lbs. The object of the experiment being only to test the apparatus, the particulars are not here stated, because the final adjustments of the system have not been made.

Previously to firing with ball, two blank charges of 4 lbs. and 8 lbs. respectively were fired, in order to try the efficacy of the screen of boards placed between the gun and the block, to protect the latter from the blast. The results have been given in the general description of the pendulums.

#### WITH THE 32-POUNDER GUN PENDULUM.

# April 29th to May 27th, 1843.

The adjustments of the pendulums having been completed, the interval between the above dates was chiefly occupied with experiments with increasing charges of powder, in order to thoroughly test the apparatus before commencing a regular series of experiments, and to devise a convenient method of making a suitable core for the pendulum block, which might be easily renewed at each fire.

The particulars of these experiments, so far as they relate to the force of the powder and the velocities of the balls, are presented, for greater convenience, in one tabular view. It is not thought necessary to give all the elements of the calculations for each change that was made in the pendulum block in the course of these preliminary trials, but it may be useful to mention the methods tried for making the cases for the sand forming the core of the block, and to state also some other particulars of the trials.

April 29th. Tried leather cases for the sand, which were made according to the description of those used in the first experiments at Metz. The leather is stretched on iron frames formed of four rings of iron 1 in. square, riveted at one end to a hoop of iron of the same size, and left loose at the other end, so that the leather case may fill the part of the block which it occupies. There are four of these cases which are filled with common building sand, the ends being closed with thin boards.

A hemisphere of lead occupies the bottom of the core; on it were placed two circular pieces of 1-in. pine board, against which the lower sand bag was intended to rest, and another disc of board was placed in the mouth of the block. The sand nearly filled the block, and a small quantity only was lost by the impact of the ball.

The lead on the face of the block, for marking the point struck, was  $3\frac{1}{4}$  lbs. to the square foot.

The screen before the gun was made of 1-in. pine boards. The grommet of the first ball, which was made of a single strand of packing yarn, was intercepted by the screen; but that of the second, which was formed of three strands, broke a piece out of one of the boards at the side of the hole made for the passage of the ball, and a part of it struck the face of the pendulum block.

The leather cases were slightly injured and required repairs. May 1st. Balls weighed and gauged.

May 2nd. The bore of the 32-pounder pendulum gun was to-day measured by means of a sliding calibre gauge, (étoile mobile,) which had been obtained from the Bureau of Artillery in Paris. This instrument was used as being more convenient and more accurate than our own of a similar kind. The measurements of the bore were made at intervals of 5 centimetres, (2 in. nearly,) commencing at 104 in. from the muzzle.

The mean of all these measurements gives 6.43 in. for the diameter of the bore. The particulars are not stated, because the results will be verified and given in detail before the commencement of a regular series of experiments.

May 3d. Another trial was made of the sand cases which had been repaired and strengthened; the bottom case was a good deal damaged by the three rounds fired to-day. The balls penetrated to the lead in the bottom of the core, and deformed it so much that it became necessary to take out the lead, in order to fill up the cavity and to fit it to its place again. When repaired, the lead weighed  $626\frac{1}{2}$  lbs., instead of the former weight of 600 lbs.

May 5th. A further trial was made of the same set of sand cases, by firing 6 rounds; this trial showed that some modification was required in the construction of the iron frames, to make them capable of long continued service.

## WITH THE 32-POUNDER GUN PENDULUM.

It will be seen, by the tabular view of to-day's experiments, that the penetration of the ball is *less* with high charges than with smaller ones; this unexpected result is explained by the great and sudden compression and solidification, as it were, of the sand in front of the ball, by which the resistance to the ball is increased when its velocity is very great.

The ball fired to-day, with the charge of  $10\frac{2}{3}$  lbs., was cracked in a meridional plane passing through the point which struck first; this ball, having been split open, was found to have, under that point and near the surface, an ovoidal cavity or air bubble, 2 in.  $\times 1.6$  in.  $\times 1$  in. in dimensions; this cavity was, as may be supposed, just at the upper end of the principal axis of the ball, which end, in all the balls, was placed outwards, or towards the muzzle of the gun; generally speaking, this front hemisphere of the ball contained the point which first struck the pendulum block, and that point was seldom more than  $45^{\circ}$  from the end of the principal axis. The balls are sensibly diminished in weight by the friction against the sand, and even when not cracked, they are often so much flattened that they will not again pass through the high gauge of their calibre.

The grommets, although weighing but  $1\frac{1}{2}$  oz., struck the screen with so much force as to break and split the 1-in. white pine boards of which it was made, and at the last fire two of the boards were rendered unfit for further use. A screen of oak planks, 2 in. thick, was substituted, and was used in all the experiments afterwards.

The frames of the first set of sand cases were made a little too large for their places; in consequence of this, the outermost case was not more than half an inch within the mouth of the block, and hence some of the sand was forced outwards by the reaction. The loss of weight from this cause could not, how-

ever, seriously affect the indications of the pendulum, as it did not exceed 10 lbs., even with the highest charge used.

May 16th. The sand cases heretofore used having been modified, by connecting the ribs of the frame together at the smaller end, as well as at the larger, by means of an iron hoop, they were again tried by firing with a charge of  $\frac{1}{3}$ . In consequence of the unyielding stiffness of this frame, some of the ribs were broken, and others bent; one of the hoops was also broken at a rivet hole, and the experiment was therefore unsuccessful.

The blank charge of  $\frac{1}{3}$  was fired to test anew the efficacy of the screen in intercepting the blast.

May 19th. Another modification of the sand cases was made and tested to-day; the hoops of one of the frames were cut into three segments, and each pair of these segments connected to gether by the ribs and by small rods of round iron; the parts of the frame were therefore free to yield to the lateral pressure, being held together in that direction only by the leather covering which was riveted to the hoops. This arrangement, further modified in some particulars, was found to answer the desired object and was adopted in the subsequent experiments, as stated in the description of the pendulums.

#### WITH THE 32-POUNDER GUN PENDULUM.

May 22nd. Some observations were made on the loss of motion of the pendulums in a given number of oscillations, as follows:

|                                          | Extent of                                           | Los                                   | s in twent                            | y vibratio            | lean loss in<br>one<br>vibration. |                               |

| Gun<br>pendulum.                         | 0 / "<br>11 01 34<br>10 07 30<br>4 32 28<br>3 44 48 | , "<br>10 34<br>10 10<br>8 28<br>8 28 | , "<br>10 30<br>10 10<br>8 36<br>8 40 | 10 00<br>8 50<br>8 16 | , ,,<br>                          | "<br>32<br>30<br>26<br>25     |
| Ballistic<br>pendulum.<br>(Block empty.) | 14 11 00<br>9 01 00<br>2 52 10                      | 13 50<br>9 26<br>6 00                 | 13 30<br>9 42<br>6 20                 | 13 10<br>9 32<br>6 10 | 13 00<br>6 20                     | 40<br>29<br>19                |

May 27th. The object of to-day's experiments was to test a set of sand cases made on frames like that tried on the 19th; the result was satisfactory with regard to this method of making the cases.

The opportunity was made use of to verify the unlooked for result of the experiment on the 19th, as to the force of the powder then tried.

Note.—In the following tabular statements the hour of the experiment is not designated as A. M. or P. M., because it was always between 9 A. M. and 6 P. M.; therefore no confusion of time can occur.

The *penetration of the ball* is the distance from the face of the pendulum block to the back of the ball.

\*The vibration of the gun pendulum, at the first fire, is recorded  $15^{\circ}$  16' 26", which was doubtless an error of observation, and it is therefore corrected to 16° 16' 26".

#### July 11th, 1843.

The pendulum experiments having been interrupted by the intervention of other duties, they were resumed to day, by weighing and gauging balls, and re-measuring the bore of the 32-pounder gun.

The points of the calibre gauge were set by a ring gauge of 6.397 in. diameter, and the measurements of the bore, reduced to inches, are as follows:

| Distance<br>from the<br>face.                                                                                        | Vertical<br>diameter.                                                                                | Distance.                                                                                              | Diameter.                                                                                    | Distance.                                                                                              | Diameter.                                                                                    | Distance.                                                                                 | Diameter.                                                                            |

Measurements of the bore of 32-pounder gun.

The mean of all these measurements, properly taken, gives 6.43 in. for the mean diameter of the bore, as heretofore used in estimating the windage of the balls; but as the seat of the ball, with charges of  $\frac{1}{8}$  to  $\frac{1}{3}$ , is between 95 and 100 inches from the face of the muzzle, the mean diameter within those limits may, with propriety, be used in estimating the windage, which will be accordingly computed, hereafter, from the diameter 6.433 in.

# July 14th, 1843.

On account of the leaden weights, for adjusting the centres of oscillation of the pendulums, becoming bruised and upset

#### WITH THE 32-POUNDER GUN PENDULUM

against the nuts which confine them to their places, so as to prevent them from sliding readily on the bolts that support them, the front weight of each set, (that which sustains the greatest pressure in the recoil of the pendulum,) has been replaced by one made of a cast iron case filled with lead.

The pendulum block having been filled, both pendulums were carefully adjusted, as follows:

|                                                                 | Weight.                                    | Dist. of cen-<br>tre of gravity<br>from axis. | Dist. of centre<br>of oscillation. |
|-----------------------------------------------------------------|--------------------------------------------|-----------------------------------------------|------------------------------------|
| Gun pendulum { Frame, with 32-pounder gun Adjusting weights     | Lbs.<br>10,500<br>667.5                    | Inches.<br>172.9<br>215                       | Inches.                            |
| Ballistic pendu-<br>lum<br>A sand bags -<br>Adjusting weights - | 9,358<br>626.5<br>9.5<br>8<br>965<br>788.5 | 170.8<br>195<br>195<br>195<br>194.34<br>219   | } 194.8                            |

For the gun pendulum, therefore, we have :

Log. 
$$\frac{2 p' g'}{12} \sqrt{\frac{G}{a'}} = 5.6620724;$$

p' being expressed in pounds, and p' in inches, the result will be in pounds and feet.

For the ballistic pendulum, regarding the point of impact as coincident with the centre of oscillation, and assigning a mean value (32.234 lbs.  $\times$ 194.5 in.) to the factor bi, of the term pg + bi, in the numerator of the formula, we have:

Log. 
$$\frac{2(p g + b i)\sqrt{Go}}{12} = 7.9800942$$

In these experiments, on the 15th, 17th, and 20th July, the penetration of the balls was, as before, about 50 in.

A self-registering thermometer was inserted from time to time into the bore of the gun, near the bottom; but the variations which were observed from the temperature of the external air in the shade are not worthy of notice, not exceeding  $4^{\circ}$ .

The loss of sand through the hole made by the ball, when the pendulum block recoils, is, with the higher charges, about 7 lbs., sufficient to cause a sensible error in the velocity, although not an error of such magnitude as seriously to affect the results, since it cannot amount to more than 1 foot in a velocity of 1600 feet. With lower charges, or with a gun of inferior calibre to the 32-pounder, the error from this cause would, it is presumed, be altogether insignificant, and it could not now be avoided without an alteration of the sand cases, which is not deemed necessary for that purpose.

By the high charges the sand before the ball was driven into the lead in the bottom of the pendulum block, so as to cause a great depression in the centre of it, and a corresponding protrusion at the edges. The sand cases were also much injured, and on these accounts only two charges of each kind of powder were fired with S lbs. At the Sth round on the 17th, the lower screw bolt, which supports the adjusting weight of the gun pendulum, was broken immediately under the nut in front of the transom. This accident was caused by the shoulder of the bolt not bearing well against the inner side of the transom, whilst the nut was screwed up hard against the outer side. The iron was also found to be coarse grained and brittle.

As it was observed that the lateral deviations of the balls have been uniformly to the *left* of the centre of the pendulum block, aslight alteration was made in the position of its shaft, and the relative position of the two pendulums was again verified. The effect of this correction is seen in the first experiments on the 20th—

#### WITH THE 32-POUNDER GUN PENDULUM.

The inaccuracies which occurred in the two last rounds on the 20th, were occasioned by a serious injury to the knife edge on the left (or eastern) end of the shaft of the ballistic pendulum, which was discovered, after the experiments, to be partially crumbled at the edge, owing to the steel having been blistered in hardening it.

In consequence of the great variation in the position of the point of impact, the two last experiments were computed separately from the others; and they would be rejected altogether, but for the conformity which is observed between the indications of the two pendulums, in comparing these with the preceding experiments.

The ballistic pendulum was dismounted and the shaft repaired without difficulty, and it was again adjusted and ready for use on the 27th.

Four sets of sand cases are now used in the service of the ballistic pendulum.

## July 28th, 1843.

Experiments in firing shells, with different kinds of powder, were commenced to-day. The shells used were made for the purpose, with a thickness of metal of 1.2 in., having a reinforce of 1.8 in. thick about the interior of the fuze hole, (after the manner of spherical case shot,) intended to give a better support to the fuze in firing with heavy charges from a long gun. The fuze hole, which is 1.2 in. in diameter, is filled with a plug of hard wood weighing about 1 oz. When floated in mercury, the shells always turned with the fuze hole up, (notwithstanding the reinforce,) and the grommets were attached to that part of the shell, so as to turn the fuze hole from the powder.

The weight of the shells was not equalized by putting any thing into them, for fear that the supplementary weight, being loose, might affect the accuracy of the results.

† Shell broken into many pieces.
‡ Cracked.
§ Not cracked.

6ð

The shells which were not broken into pieces, were generally found in the bottom sand bag; those which were broken, in the third bag. There was no uniformity in the position, with reference to the fuze hole, of the part of the shell which first struck the pendulum block; it was sometimes at the point opposite to the fuze hole, sometimes at the fuze hole, and at intermediate points. When the shells were broken in the pendulum block, it was necessary to renew the bottom sand bag only after about three rounds; if not then removed, the sand in it became so closely packed as to occasion considerable difficulty in extracting it.

With the charge of 4 lbs, the diameter of the cartridge is greater than its length or height, which sometimes caused it to turn over, notwithstanding the care taken to insert it, by pushing it with the handle of the rammer; these cases are noted in the column of remarks.

The first round, on the 3d of August, was fired for the purpose of trying the efficacy of substituting, in these high charges, for the bottom sand bag, a case filled with soft bricks. The ball did not penetrate through this case, but the bricks were finely pulverized, and compressed so hard against the sides of the block that they were removed with difficulty, and the dust from them was exceedingly inconvenient.

After the cartridge for the 9th round, on the 3d, had been inserted, it was found that there was no shell at hand, and as the hour was late, the shell used for the 7th round was fired over again, without being gauged; the part of the shell which struck first was the same as before, (opposite to the fuze hole,) and it was afterwards found to be enlarged in the other direction to 6.27 in.; one-half of this increase of diameter has been attributed to each fire.

In computing the initial velocities of the balls, by the ballistic pendulum, in these experiments, a constant value is as-

### with the 32-pounder gun pendulum.

signed to the factor bi, (in the numerator of the formula,) which is made equal to the mean distance of the points struck, multiplied by the mean weight of the shells, = 194.5 in.  $\times$ 23.763 lbs.

Hence, Log. 
$$\frac{2(pg+bi)\sqrt{Go}}{12} = 7.9797518$$

The measures being in inches, the result will be in feet. By calculating the velocity by the correct formula, for a case of extreme variation from this mean value of b i, (such as the case of the 10th round on the 4th of August,) it is found that the error caused by the transformation of the formula, and by assigning a mean value to b i, does not exceed  $\frac{4}{10}$  ths of a foot; in ordinary cases it may therefore be safely disregarded.

Having ascertained that the lateral deviations of the ball from the axis of the pendulum block are unimportant, they will no longer be recorded, except in extraordinary cases.

In the course of the experiments on the 8th, it was observed that the shaft of the ballistic pendulum shifted a little, in its V's, towards the right hand or west end, in consequence perhaps of the balls striking generally on the left side of the centre of the block. In order to prevent the shoulder of the knife edge from bearing against its seat, the shaft was set back to its place, which was done, without difficulty, by means of a wedge acting on the end of a *shore* placed between the pendulum block and the western pier.

For the calculation of the velocities in these experiments :

$$\log \frac{2(pg+oi)}{12}\sqrt{Go} = 7.9800953$$

## August 24th, 1843.

MEASUREMENTS OF THE BORE OF THE 32-POUNDER GUN.

The measurements are of the vertical diameter, commencing, as on the 11th of July, at the distance of 104.36 in. from the face of the muzzle.

| Distance.            | Diameter.     | Distance.      | Diameter.     | Distance.               | Diameter.            | Distance.              | Diameter.     |

| 94.51                | .432          | 80.73          | .429          | 59.07                   | .425                 |                        |               |

These measurements agree, as nearly as could be expected, with those on the 11th July, and most of the differences may even arise from variations in the use of the instrument, or from

#### WITH THE 32-POUNDER GUN PENDULUM.

the points not resting precisely on the same spots as before. The *diminutions* of diameter at some points cannot be regarded as evidence of inaccuracy in the measurements, as they may have been caused by bruises from the balloting of the ball. The decided increase of diameter at about 100 in. from the muzzle, or 7.6 in. from the bottom of the bore, indicates a depression of 0.005 in. at that point which is the seat of the ball with a charge of 4 lbs., with which charge 67 rounds have been fired since the former measurement of the bore.

In estimating the windage, the diameter of 6.433 in. will still be used.

\*Ball turned over in the gun.

73

For the experiments on the 26th August, the shells were filled to a uniform weight (intermediate between that of the empty shell and the solid shot) with bits of lead and iron filings, in order to obtain additional data for comparing the velocities of balls of different densities, fired with the same charge of powder.

The pieces of lead, and even the iron filings, were found to be compressed into a solid mass by the concussions.

The 7th round was fired for the purpose of trying a case filled with *hard* bricks, in place of the bottom sand bag; this was found to be of better service than the soft bricks before tried, and it was more easily extracted, on account of the bricks being less pulverized.

For the experiments on the 15th September, the balls were brought to a uniform weight by pouring lead (when the ball was too light) into a hole drilled at the upper extremity of the principal axis; this hole was then stopped with an iron plug turned to fit it, driven in hard. No grommet or wad was used, but the ball was supported in the axis of the bore by means of four little wings of sheet iron, about  $\frac{1}{2}$  in. long, attached to the ball in the direction of its principal axis; these wings were too short to prevent the ball from turning over in some instances, as noted in the remarks.

The tin bands mentioned in the column of remarks were straps of tin, 0.2 in. wide, with four drops of solder on them, intended to support the cartridge also in the axis of the gun, by keeping it clear of the bottom. The weight of these bands is included in that of the cartridge; they had probably no influence on the force of the charge.

In the firing, the iron plugs were driven down to the bottoms of the holes in the balls, forcing out the lead in the holes, although the plugs and the holes were both made tapering.

For the experiments on the 16th and 21st of September,

## with the 32-pounder gun pendulum.

75

with balls of different windages, the balls were *turned* by means of an accurate and simple circular rest adapted to a lathe, and by means of the holes bored for the arbor they were adjusted in weight, like those used on the 15th. Balls of large size, for turning, were obtained from the Columbia foundry, near Georgetown, D. C., and they proved to be remarkably sound and free from air bubbles; they are of greater specific gravity than the hammered balls made for these experiments at West Point foundry.

Grommets were attached, in the usual way, to all except the largest balls, these being made to fill the bore as nearly as it was thought safe for firing. It is remarkable that all these balls struck the pendulum block with the plugs foremost; the plugs were forced, as before, to the bottoms of the holes in which they were inserted, expelling the greater part of the lead from the holes.

After the experiments of the 21st, an attempt was made to fire again one of the balls of 6.42 in. diam. which was used on the 16th, and which had been dressed over with the file and passed through the same gauge as before; but the ball stuck in the bore at about 77 in. from the muzzle, and could be extracted only by screwing a rod into it. The experiment was thought too hazardous to repeat.

#### November 1st, 1843.

In order to repeat, with more care and with different powder, the experiments on ranges, &c., the pendulum block was dismounted, and a frame to receive a sheet of lead was attached to the front pair of suspension straps, to mark the point struck by the ball at that distance from the gun; the other arrangements for observing the ranges were the same as those on the 7th and 17th of April.

Experiments on ranges,

#### WITH THE 24-POUNDER GUN PENDULUM.

#### EXPERIMENTS WITH THE 24-POUNDER GUN.

## February 1st, 1844.

On account of the prompt destruction of the sand cases for the core of the pendulum block, by firing the 32-pounder balls with high charges, it was determined to lay aside the 32-pounder gun for the present, and to continue the experiments with a 24-pounder, with which higher proportional charges might be conveniently used. In order to give this gun such a weight as to reduce its recoil within moderate limits, with the highest charges which it may be desirable to use, and at the same time to make the piece of undoubted strength to resist a repetition of such charges, the exterior form and dimensions of the 32pounder gun were preserved; and as the piece was intended for use exclusively with the pendulum, it was not furnished with trunnions.

This 24-pounder gun, which is of iron, like the 32-pounder, was cast at West Point foundry; the metal has the appearance and all the characteristics of the best quality of gun iron. The length of the bore is the same as that of the siege and garrison 24-pounder, 9 feet; diameter of the vent 0.175 in.; weight 7,935 lbs.

Before replacing the pendulum block some experiments on ranges were to be made with the 24-pounder gun, in the same manner as with the 32-pounder; and for this purpose the necessary arrangements were made to-day. It was found that, on account of the more accurate fitting of the 24-pounder gun in the collars of the suspension straps, its axis deviated less than that of the 32-pounder from a plane perpendicular to the axis of the shaft, and a thinner washer was therefore substituted for the one before introduced between the straps on the right hand end of the shaft.

## February 2nd, 1844.

The experiments on ranges were made to-day. The river being covered with strong ice, the points struck by the ball were marked by observers stationed on the ice, and the ranges were afterwards measured; they struck at too low an angle to break the ice, in which they left a distinct mark. The loss of two observations was probably caused by the balls striking in the channel opened by the steamboat.

The cartridge bags used in the experiments with the 24pounder gun, are made, like those for the 32-pounder, of twilled woollen stuff; they are made with circular bottoms, and sewed on a cylinder 5.35 in. in diameter.

Experiments with the 24-pounder

#### WITH THE 24-POUNDER GUN PENDULUM.

The balls were fixed with grommets and leather straps as before, and the grommets were placed at the upper or lighter part of the ball floated in mercury, that part being turned towards the muzzle of the gun; mean weight of the 12 grommets and straps used to-day, 0.084 lbs.

The adjusting weights on the gun pendulum were the same as for the 32-pounder gun; the additional weight of 246 lbs., placed symmetrically about the axis of the gun, does not appear to have sensibly affected the height of the centre of oscillation of the system; the exact determination of that centre was left for a more favorable season.

gun pendulum, February 2nd, 1844.

## March 11th, 1844.

The pendulum block having been remounted, the requisite adjustments of the two pendulums were verified.

In the gun pendulum, as left on the 2nd of February, the centre of oscillation was found to be still in the axis of the gun, or at 195 in. from the knife edges.

The weight of the gun being 246 lbs. greater than that of the 32-pounder, and this weight being distributed symmetrically about the axis, we have:

$$p' g' = 1,958,963 + 246 \times 195 = 2,006,933;$$
  
Hence, Log.  $\frac{2 p' g'}{12} \sqrt{\frac{G}{o'}} = 5.6725937.$ 

The first hemisphere of lead in the pendulum block having been much bruised and deformed, it was replaced by another weighing 481 lbs.; with this change, and a slight alteration in the core, the height of the centre of oscillation of the pendulum was again determined; but as the pendulum was used in this state only for the three rounds fired on the 12th, the elements of the calculation are not set down.

#### March 13th, 1844.

The ballistic pendulum block was charged, and the centre of oscillation of the system adjusted, as follows:

|                                                             |             |   |   | Weight. | Centre of gravity. |

Consequently, the moment of the pendulum, p = 2,079,250.

**S2** 

#### WITH THE 24-POUNDER GUN PENDULUM.

In this condition, the pendulum was found to make 1000 oscillations in 2234 seconds, therefore o = 195.14.

In the experiments with solid shot, the mean value of b is 24.16 lbs., and that of i will be found nearly 195.03 in. Hence, in the formula for the velocity of the ball, we have:

Log. 
$$\frac{2(p g + b i)}{12}\sqrt{Go} = 7.9791267.$$

The bore of the 24-pounder gun was carefully measured today, the points of the calibre gauge being set to 5.815 in., the diameter at the muzzle.

.

The powder designated by No. 1 & 2, is a mixture of the two sizes of grain denoted by Nos. 1 and 2 respectively; the difference between these sizes of grain appears, by the experiments of August 12th, 1843, to be inappreciable, so far as regards the force of the charge in the gun, and they were therefore mixed together, (or not sifted out separately,) for the purpose of economizing the powder.

The balls for the experiments on windage were accurately turned and adjusted to the weights set down for them; most of them were turned from the large 32-pounder balls obtained from Columbia foundry, which, as before observed, are of remarkably sound iron, and of greater density than those cast at West Point foundry; this explains, in part, the marked difference in the weight of the turned balls of 5.7 in. diam., and the common shot of 5.68 in.; it was observed, too, that the former were not cracked by being fired against the pendulum block with a velocity of 1700 ft., whilst the latter were very often cracked with a velocity of little more than 1400 feet.

In consequence of a slight accidental derangement of the arc of the ballistic pendulum, which it is not necessary to particularize, some doubt was thrown on the result of the 6th round on the 20th, although the indications of the two pendulums correspond very nearly; a fourth round of the same powder and ball was therefore tried on the 22nd.

For the 1st and 2nd rounds on the 20th, the sand bags for the pendulum block were filled with very fine, but pure, sand; and for the 3d round, with coarse sand of a similar kind; but no difference worthy of note was remarked in the penetration of the shot. Habitually the same sand is used over repeatedly for filling the bags, adding to it, however, a portion of fresh sand.

A striking difference is remarked in the appearance of the residuum left in the bore by the combustion of the severa

## with the 24-pounder gun pendulum.

kinds of gunpowder; that of powder A is black, but marked with streaks and spots of a blood red color; that of powder F is of a bright yellow color, softer and more easily removed than the other; the residuums of the powders B, C, and D, are of a dark grey, or slate color, and very hard; the quantity of dirt left by the powders C and D, is greater than that from the other kinds.

An additional quantity of 5 barrels of powder A was received from Frankford Arsenal, on the 14th inst.; it is from the same lot as the first 5 barrels received, and was originally inspected and received on the same day, 19th July, 1837.

In these experiments on balls of different weights, marble and wooden balls were tried, because it was thought that shells made thin enough to reduce their weight to 9 or 10 lbs. would be broken in the gun with a charge of 4 lbs. The first lignum vitæ ball passed through the hole in the screen, but was so much broken at the instant of striking the block as to tear the sheet of lead to pieces; the whole of the ball appeared, however, to have entered the block. The second of these balls = and another fired on a subsequent day, were broken in the gun = and fragments of them went through the 2-in. oak plank of the screen.

The two large balls, for the 16th and 17th rounds, were turned, and their weights reduced as much as practicable by

WITH THE 24-POUNDER GUN PENDULUM.

\* Broken in two. † Cracked. § Not cracked.

boring holes in them, and enlarging these holes at the centre of the balls; they were inserted in the gun with the axis of the hole in the axis of the gun, by screwing a small rod into the plug with which the hole in the shot was stopped.

There was some peculiarity, which cannot be explained, about the 9th round of to-day's experiments. It is almost certain that there was no error in the charge; yet its force appears to have been, in a marked degree, superior to that of the other two charges with similar balls, and several persons at a distance from the gun asked the cause of the remarkable sharpness of the report. Two other rounds were fired, with the same weight of powder and ball, on the 4th April. See the next table.

# Remarks on the experiments of April 17th, 22nd, and 23d.

April 17th. The lead in the bottom of the pendulum block having again become much deformed, there was substituted for it to-day a block composed of 4 parts of lead and 1 of tin, in order to make it harder and more capable of resisting the compression caused by the balls. The weight of this block is  $501\frac{1}{2}$  lbs., and an oak board weighing 8 lbs. is placed over it; the sheet lead on the face of the pendulum weighs  $7\frac{1}{2}$  lbs.; the four sand bags weigh 230 + 238 + 230 + 238 = 936 lbs. The moment of the pendulum is therefore :

 $pg = 9358 \times 170.8 + 516 \times 195 + 936 \times 194.34 + 917 \times 219 = 2,081,691$ ; and the centre of oscillation being still at 195.14 in. from the axis, we have:

Log. 
$$\frac{2(pg+bi)}{12}\sqrt{Go}=7.9796345.$$

In the experiments to-day it was intended to compare the effects of using various kinds of wads. The hay wads fitted tight in the bore of the gun; the junk wad was not very tight, and it was well covered with tallow to diminish its friction, the intention being to try also some wads that were not greased; but in firing with two of the hay wads and one junk wad, the deviations of the ball at the face of the pendulum block were so great that the experiments were discontinued, for fear of striking the iron part of the block; the ball fired with the junk wad narrowly missed the edge of the face plate, and nearly destroyed the outer sand bag.

In firing the wooden and marble balls the outer sand bag was omitted, and its place supplied by iron rings of the same weight.

The bags for the cartridges of 5 in. diam. were made, in other respects, like those before used.

As the bore of the gun was not supposed to be sensibly enlarged, it was not again measured until the 18th June, when

#### WITH THE 24-POUNDER GUN PENDULUM.

there was found to be an enlargement, at the seat of the shot, of about 0.01 in.; one-half of this enlargement has been attributed to the effect of the firing previously to the present date, and the windage is accordingly estimated by the diameter of 5.82 in.

April 22nd. The percussion primers used in to-day's experiments were wafers, which were fired by means of a lock arranged for the purpose by Mr. Hidden; the lock has a strong spring, but it is set to go off at a slight touch; so that, by pulling the trigger, no motion is communicated to the pendulum; the object was perfectly accomplished and the lock never failed to fire the charge.

The cartridges were filled on the 18th, since which time the weather has been wet.

April 23d. The anomaly in the height of the cartridge for the 7th round to-day, can be explained only by supposing that a bag for a cartridge of 5 in. diam. was inadvertently used.

The cartridge bags for the 37th and 38th rounds were made on a former of very nearly the diameter of the bore, and after they were filled, the bags were closed by folding down and sewing the stuff, so that the powder may be regarded as occupying the least possible height in the bore of the gun.

For the 39th round, the core of the pendulum block was formed of a wooden case, or barrel, filled with sand; the penetration of the ball was the same as before; the staves of the barrel were pressed so closely against the sides of the block as to make it difficult to remove them. This barrel of sand weighed 722 lbs., and the centre of oscillation of the pendulum, with this core in the block, appeared to be at 194.8 in. from the axis.

One object of to-day's experiments was to ascertain if the effect of closing the vent of the gun is appreciable by its influence on the velocity of the ball.

The arrangement of the apparatus for closing the vent was suggested by that proposed for Mr. Colson's eprouvette, in the 4th No. of the "Mémorial de l'Artillerie."

The apparatus is represented in PLATE III; it consists of a block of wrought iron, hollowed out on the under part to fit the gun, and having a small hole through it to correspond with the vent of the gun when the block is in place; this block is bored longitudinally, to receive a hollow conical plug of cast steel which is ground to fit tight in its place when pushed down to the bottom of the bore in the block; the plug has also a transverse hole, or vent, through it, which corresponds with that in the block when the plug is drawn out about 0.4 in. from the

WITH THE 24-POUNDER GUN PENDULUM.

\*Vent stopper did not act perfectly.

bottom of its lodgement in the block, so that, in that position, there is a direct communication open with the bore of the gun. The hollow plug is charged with a small quantity of fine, quick (sporting) powder, over which a paper wad is rammed; it is then placed in the position above described, and the charge is fired by means of a small piece of quick match inserted in the upper part of the vent in the iron block; the charge in the gun is ignited with certainty, although there is no priming in the proper vent of the piece; but before the explosion of the charge the conical plug has recoiled to the bottom of its lodgement, and effectually closed the vent, as is proved by the distinct impression made on the under side of the plug by the gas which tends to escape in that direction.

After the discharge, the plug is again driven out, through a hole made for the purpose in the bottom of the iron block; the plug should be fitted so as to bear against the bottom at nearly the same time that it becomes wedged in its seat, otherwise too great a force is required to drive it out; on the other hand, if the plug touches the bottom before it binds on the sides, it will fly out again, and not produce the desired effect; the latter case occurred at the 5th round in to-day's experiments.

The gun being without a lock piece, or other projection at the vent, the vent stopper was secured to it by a broad band of  $\frac{1}{2}$ -in. iron, which was put on hot and keyed underneath; but unfortunately, with the view of making it fit more closely to the gun, the workmen put a piece of sheet lead between the block and the gun; this lead was expelled with great force at the first discharge, and the tightness of the joint was consequently impaired, as the vent stopper was jarred from its place and had to be refitted at each fire; there was evidently some escape of gas between it and the surface of the gun, but it is believed the loss was quite inconsiderable.

The weight of the vent stopper and band was 41 lbs. For the first round to-day the core of the pendulum block was formed (like that for the last round on the 23d) of a barrel filled with sand. For the other experiments the leather cases were used as before; the impression made by the balls fired with the charge of 10 lbs. seemed to be but little greater than that with 6 lbs.

Up to this time the vent of the gun had not been particularly examined, as no alteration of the exterior orifice appeared to have occurred, and as it was not supposed that the vent could be much enlarged by the comparatively small number of discharges which had been made; but after the experiments today, it was observed that the exterior orifice of the vent was sensibly enlarged, and its form no longer round. A careful

examination was therefore made, when it was found that the exterior opening of the vent was about 0.25 in., and that it was enlarged gradually to the bottom, where the impression of the opening, taken with wax, was of the form and dimensions represented in Fig. A, PLATE III. By the necessity which this enlargement of the vent produced, of bouching the gun, an opportunity was soon presented of perfecting the adjustment of the vent stopper, which was accordingly done in the manner represented in the drawing, and described under date of July 16th.

It may be well to remark that no sensible vibration of the gun pendulum is produced by firing the charge in the vent stopper alone.

# May 28th, 1844.

In consequence of the great deviations in the direction of the balls, occasioned by the use of wads, in the experiments on the **17th** April, I was induced to try further experiments on this subject.

For this purpose I used a 24-pounder gun, which was mounted on a garrison (barbette) carriage, near the ballistic pendulum; the chassis was blocked up underneath, and a block of wood was substituted for the elevating apparatus, to support the breech of the gun, so that the bore might be accurately levelled at each fire, and directed uniformly alike.

At 50 feet from the muzzle of the gun was erected a frame for a target, of poplar boards  $\frac{2}{3}$  of an inch thick and 2 feet square, the centre of which was in the prolongation of the axis of the bore when level; these boards were renewed at each fire.

A second target was placed on the wharf, (see PLATE 1,) at 1004 feet from the muzzle of the gun, and the direction of the line of fire marked on it.

The axis of this gun is 6.75 in. above that of the pendulum **gun**, and consequently 17.62 ft. above the surface of the wharf.

The diameter of the bore of the gun is 5.833 in. Length of bore is 108 in.

The balls were all of 5.69 in. diameter.

The cartridge bags were like those used for the pendulum experiments.

The points struck by the balls at the first target were observed with the view of comparing the results with the theo-

\*This shell made an oval hole in the lead on the face of the pendulum block, in consequence probably of the shell undergoing a change of form in the gun.

### June 18th, 1844.

After the experiments to-day, the vent of the gun was again examined; the exterior orifice is perceptibly, though slightly, more enlarged; the form and size of the interior opening are represented by Fig. B, PLATE III.

The bore of the gun was again measured, in the same manner as on the 13th of March, with the following results:

| from .                                                                                                                   | DIAM                                                                                                  | ETER.                                                                                                                  |                                                                                                                   | DIAMI                                                                                  | STER.                                                                                                          |                                                                                                                   | DIAM                                                                                                           | TER.                                                                                   |

Measurements of the bore of the 24-pounder gun.

A comparison of these measurements with the former shows an enlargement of the bore to a mean diameter of about 5.825 in., at the seat of the shot with a charge of 6 lbs.; this diameter has therefore been used in estimating the windage of the balls, in the experiments made since the 15th inst.

#### WITH THE 24-POUNDER GUN PENDULUM.

### July 16th, 1844.

Since the experiments of the 18th of June, the 24-pounder gun has been bouched with a copper vent piece, having a vent 0.175 in. in diameter; this vent piece was left projecting above the gun for the purpose of attaching to it the vent stopper used in the experiments of April 25th.

The vent stopper was screwed on the top of the vent piece, in the manner represented in PLATE III. This arrangement furnished the means of repeating, in a more satisfactory manner, the experiments on the effect of closing the escape from the vent.

In these experiments, the impression of the blast on the under side of the vent stopper showed that the vent was perfectly closed at the 1st, 2d, 3d and 6th rounds; a distinct impression, but not equally strong, was made at the 4th and 5th rounds; but as the conical plug was, in those two instances, thrown out of its seat, by striking against the bottom of it, some doubt may exist as to the vent having been closed at the time of the explosion of the charge in the gun.

The vent being now in the same condition as at the beginning of the experiments with this gun, (on the 12th of March,) three charges of powder A were fired in order to determine what effect on the velocity of the ball might be traced to the sensible alteration which has taken place in the diameter of the bore about the seat of the charge.

The trial of powder W, on the 17th of July, was with the view of ascertaining the initial velocity of the balls fired with that powder, in the experiments with wads, on the 28th and 29th of May.

# WITH THE 24-POUNDER GUN PENDULUM.

113

•

\*Ball broke; has a large cavity in it.
†Grommet struck the pendulum block.
†These balls were strapped without being floated in mercury.

# July 22nd, 1844.

The measurement of the bore of the 24-pounder pendulum gun was verified with an instrument made at Washington Arsenal, after the model of the French instrument heretofore used for that purpose.

The moveable points of the instrument were set by a ring gauge of 5.82 in. diameter. The vernier is graduated to read *hundredths of an inch*, and these divisions are readily subdivided by the eye. The results of this measurement are as follows:

| Dist. from<br>muzzle. | Vertical<br>diameter.        | Distance.            | Diameter.                            | Distance.            | Diameter.                    | Distance.            | Diameter.                            |
|-----------------------|------------------------------|----------------------|--------------------------------------|----------------------|------------------------------|----------------------|--------------------------------------|
| In.                   | In.                          | In.                  | In.                                  | In.                  | In.                          | In.                  | In.                                  |

### 116 DESCRIPTION OF THE MUSKET PENDULUM

#### III. EXPERIMENTS WITH THE MUSKET PENDULUM AND ITS BALLISTIC PENDULUM.

### DESCRIPTION OF THE PENDULUMS. (PLATE IV.)

These pendulums, like the large ones, are constructed on the model of those used at the powder works in France, for the drawings of which I am likewise indebted to the kindness of Messrs. Dupont, of Delaware. The arrangement of the apparatus being represented in the accompanying drawings, a brief description only will be requisite.

### The musket pendulum.

The frame for supporting the musket barrel consists of two parallel bars of iron, connected together by a transom at each end; each of these bars has an ear containing a trunnion hole to receive the trunnions of the musket barrel, which are fitted into a solid cylinder of iron that is substituted for the breech screw of the musket; the barrel is held in its place and adjusted, by means of four set screws passing horizontally through the bars of the frame, one pair near each end of it; a fifth set screw, passing vertically through the front transom, serves to adjust the musket barrel in a horizontal position when the frame is horizontal.

This frame is suspended by means of four iron rods; at the lower end of each rod is a shackle which is bolted to the transoms of the barrel frame, and a similar shackle serves to connect the rods above with the shaft of the pendulum; the screws cut in the ends of each rod, to unite it with the shackles, are right and left hand screws, respectively, so that by turning the rod, the distance of the frame from the shaft is increased or diminished at pleasure, and, in this manner, the height of the axis of the barrel is readily adjusted; when once adjusted, the

#### AND ITS BALLISTIC PENDULUM.

rods are held fast by nuts screwed up against the shackles, to prevent the rods from turning.

The shaft of the pendulum is a flat bar of steel, at each end of which is a knife edge well hardened and tempered.

The parts of this pendulum are so arranged that, when it is at rest, the frame is nearly horizontal; the slight adjustment requisite for making it exactly horizontal is effected by means of leaden weights, supported by a small bolt screwed into the rear transom of the frame; a thumb-screw nut serves to keep these weights in place, by pressing them up against the transom.

The knife edges of the shaft rest in V's of hardened steel, which are set in cast iron hangers connected by a plate, and this plate is secured by four bolts to another plate, also of cast iron, which is firmly bolted and braced to a brick wall.

The arc of vibration is measured on a brass limb, which is clamped to an iron plate, on which it can slide in a circular direction, so that the zero of the limb may be properly adjusted; the iron plate is supported by a frame of wrought iron secured to the wall, and furnished with four set screws which serve to adjust the arc to the proper distance from the knife edges; a slider moves in a groove in the brass limb, and is retained at any part of the limb by the pressure of a slight spring. In the vibration of the pendulum, the slider is moved by an index attached to a bar which is fastened, at a suitable height, to two of the rods of the pendulum frame.

The radius of the graduated arc is 57.3 in.; each degree of the brass limb is divided into six parts, and the vernier on the slider subdivides these parts into minutes.

### The ballistic pendulum.

This pendulum is composed of a hollow, conical block of bronze, suspended by two iron straps to a shaft formed of a flat bar of steel, with knife edges like those of the musket pendu-

Digitized by Google

### 118 DESCRIPTION OF THE MUSKET PENDULUM

lum; a brace between the straps serves to stiffen them, and into one end of this brace is screwed the index which moves the slider on the brass limb for measuring the vibration of the pendulum.

An iron clamp, of a simple construction, presses a circular wooden plate against the face of the pendulum, and the point struck by the ball is marked by the perforation of this wooden plate.

In the pendulum represented in the French drawings, the core of the pendulum block consists chiefly of a block of lead against which the ball is fired, and which is renewed at each shot.

The inconvenience which I anticipated from the fragments of the lead and the ball, and the trouble attending the renewal of the leaden core, induced me to try other methods of forming the core, as will be seen in the Journal of the experiments. The result of these trials was the adoption of a core composed of:

1st. A block of hard wood turned to fit the bottom part of the pendulum block.

2nd. A conical block of lead, faced with a plate of iron, occupying nearly the centre of the core.

3d. A block of hard wood, turned and cut to such a length as just to fill the pendulum block, and to bear against the face plate. In my experiments these blocks were made of well seasoned hickory, and they were accurately adjusted to the proper weight by boring holes in them, which were, when necessary, filled with plugs of lead; the wood being exceedingly well seasoned, (more than 20 years old,) was nearly uniform in weight, and required little alteration after being turned; in order to avoid the alterations that might have been produced by changes in the hygrometric state of the air, the weight of the blocks was generally adjusted on the day on which they

#### AND ITS BALLISTIC PENDULUM.

were used; this weight is such as to keep the axis of the block horizontal when the pendulum is at rest.

As there was but very little variation in the position of the point struck by the ball, it was not requisite to renew the wooden face plate at each fire; the same plate was therefore used for many rounds, the balls always striking in a hole 1 in. in diameter, in the centre of the plate.

The arrangements for suspending the ballistic pendulum, and for measuring the vibration, are the same as those for the musket pendulum. The distance between the axes of the two pendulums is 10 ft.; the muzzle of the musket is 6 feet from the face of the pendulum block.

A screen of boards, having a hole 2 in. in diam. for the passage of the ball, is placed two feet in front of the ballistic pendulum, to intercept the wads and the blast of the charge.

The musket pendulum frame is very stiff, having perhaps an unnecessary degree of strength; but the suspension straps of the ballistic pendulum are subject to a good deal of lateral vibration, as stated in the Journal.

The pendulums are attached to the south side of a brick wall, and covered by a wooden shed, occupying the position indicated on the plan—PLATE I.

### Service of the pendulums.

After numerous experiments on the manner of loading the musket barrel, it was determined to adopt nearly the same method that is pursued in ordinary service.

The charges are weighed, with an accurate balance, and put into small tin canisters; to load the piece, the charge is poured into a small copper or tin charger attached to the end of a ramrod; the musket barrel is inverted over it, the vent being previously stopped with a brass wire; the barrel and charger are

### 120 DESCRIPTION OF THE MUSKET PENDULUM

then again reversed together, and the charge of powder is shaken out into the bottom of the barrel.

The ball is wrapped, as for a common cartridge, in a rectangle of ball cartridge paper, 3 in.  $\times$  4.5; the paper is choked tight over the ball, and also slightly choked below, to prevent the ball from falling out. Instead of merely inserting the ball, with the paper, over the powder, the paper is first formed into a wad, in a manner nearly uniform, by putting the cartridge case, with the paper down, into a piece of musket barrel, and pressing on the ball with a wooden rammer, which crumples the paper neatly into a sort of sabot. In loading, the paper is inserted next to the powder; the ball is followed up with the rammer which is of steel, and weighs  $1\frac{1}{2}$  lbs.; this rammer is then raised 6 in. and let fall on the charge once; the height of the charge was always measured by a graduation on the rammer, in order to guard against error in loading.

, The common cast balls being generally rough and unequal in size and weight, I had balls prepared for these experiments by compression, by means of dies adapted to an ordinary punching machine for punching iron plates; by this simple arrangement, balls were made very nearly exact, in size, form and weight. Those used in most of the experiments were of the present regulation size, 0.64 in diameter, and they were gauged with rings of the diameters of 0.642 in. and 0.6385 in.; the average weight of 1151 of these balls was 397.523 grs.; many of them were weighed separately, and found to be between 396.5 grs. and 398.5 grs.

After each discharge, the musket barrel is taken from its frame and wiped carefully with dry rags; it is washed generally after five rounds.

ŝ

The set screws on one side of the frame being undisturbed, the direction of the barrel requires no other adjustment, after

#### AND ITS BALLISTIC PENDULUM.

being once set, than to be pressed up gently, but firmly, by means of the screws on the other side of the frame.

The charge is fired with a piece of quick match in the vent.

The wooden block into which the ball is fired is 4.5 in. long; with a charge of even 100 grains, the musket ball generally penetrates through this block (of hickory wood) and is flattened against the iron plate with which the lead block is faced; the lead and the wooden core are usually wedged slightly against the sides of the block, and have to be driven out through a hole left in the bottom of the pendulum block for that purpose.

ELEMENTS FOR COMPUTING THE VELOCITY OF THE BALL.

The formulæ for this purpose are the same as those before given for the large pendulums.

The constant elements of the calculations, in the usual condition of the pendulums, are as follows:

#### 1. For the ballistic pendulum.

|                                                               |

### 122 DESCRIPTION OF THE MUSKET PENDULUM

Dist. of the axis of the block, or usual point of

| impact, fi       | om the    | knife edg  | - es                          | i = 79. in.                               |
|------------------|-----------|------------|-------------------------------|-------------------------------------------|
| Weight of t      | he ball o | of 0.64 in | n. diameter,                  | b = 0.05679 lbs.                          |
| Do               | do        | 0.65       | do                            | = 0.05861                                 |
| $Log. 2\sqrt{p}$ | g+bi) (1  | go+bi2     | ) $\overline{G}$ for ball 0.6 | 4  in. = 4.3279424<br>5 in. = $4.3142795$ |
| 2005             | 12 6      | i          | for ball 0.6                  | 5  in. = 4.3142795                        |

The variations in the point of impact being very small, its distance has been regarded as constant, in the denominator as well as in the numerator of the formula; but, in case of any considerable variation, the correction is easily made in the above logarithms, by adding or subtracting, as the case may be, the difference between the logarithm of 79, and that of the true value of i.

#### 2. For the musket pendulum.

Weight of the suspension frame78.26 lbs.Weight of musket barrel and breech9.12Weight of adjusting weights1.56

Total weight of pendulum - p' = 88.94 lbs. Dist. of centre of gravity from knife edges g' = 43.85 in. Time of 1000 oscillations - 1297 sec. Dist. of centre of oscillation from knife edges, o' = 65.77Force of gravity - G = 385.86Dist. of axis of barrel from knife edges i' = 79.

$$\operatorname{Log.} \frac{2 \, p' \, g' \, \checkmark \, G \, o'}{12 \, i'} = 3.1175821$$

Mean weight of the rectangle of cartridge paper,

 $(3 \text{ in.} \times 4.5 \text{ in.})$  in which the ball is wrapped, 10.5 grs. Diameter of the bore of the musket barrel - 0.69 in.

As I have before remarked, in the discussion of the formule for the velocity of the ball by the recoil of the cannon pendulum, I do not find the same coincidence with the results given

#### AND ITS BALLISTIC PENDULUM.

123

by the ballistic pendulum, in applying that formula to the musket pendulum. No value that can be assigned to the quantity N in the formula, (see page 32,) will produce results of equal accuracy when applied to different kinds of gunpowder, and in all cases, it appears that the value of N is much smaller for the musket than for the cannon pendulum. This would appear to be the natural consequence of variations in the force or intensity of the flame produced by the combustion of various kinds of powder; that powder which acts with the greatest force on the ball whilst it is near the bottom of the musket barrel, having been more thoroughly consumed at the first moment of ignition, will probably have a smaller proportional expansive force remaining, after the ball has left the barrel, than the powder which, burning with less energy at first, continues to develope its force as the ball passes through the barrel; and this difference of effect becomes greater in proportion as the length of the barrel is increased, and the absolute quantity of powder in the charge diminished.

It may be said, also, that similar conditioner for the estimate of the velocity attributed to the gaseous fluid resulting from the combustion of the powder; in our formula it is supposed that the mean velocity of this fluid behind the ball, or the velocity of its centre of gravity, is *half* that of the ball; but it is quite probable that when a small charge of very strong powder is burnt in a long barrel, (long in proportion to its calibre,) this estimate of the mean velocity of the flame is too high. This correction is also suggested by Hutton, who thinks that we should perhaps be nearer the truth in estimating the velocity of the mass of the flame at *one-third* that of the ball.

There is still another cause of error in the application of this formula to the musket pendulum, resulting partly from the method which I have adopted for loading the musket barrel. It will be remembered that, in the first term of the denominator 16

16

Digitized by Google

of the formula, it is supposed that the elastic fluid acts on the ball as it would on a surface equal to that of a great circle of the ball; but the paper wad, which is placed between the powder and the ball, must tend to increase the surface on which the fluid acts, and the same effect is also produced by the cartridge paper which is wrapped around the ball; these circumstances make it impossible to appreciate exactly the measure which should be assumed for the diameter d, which, in the formula for the pendulum, represents the diameter of the ball itself, but should here be something greater, since the windage is partly destroyed; moreover, it is almost impossible to measure the true windage of each ball, and a slight error in this respect becomes appreciable in the value of the term  $\frac{D^2}{d^2}$ .

The method of loading, which is here referred to, was adopted, because it corresponds very nearly with that habitually practised in the service of the musket, and because it gives, with the same charge, a greater velocity to the ball than could be obtained by placing the ball next to the powder, with the wad on top; that this method by no means annihilates the windage, is shown by the marked increase of velocity produced by using a larger, though a heavier, ball.

But, whatever may be the cause, I have not found the formula for the velocity of the ball by the recoil of the musket pendulum, to represent correctly the results of my experiments, and I have therefore contented myself with recording the moment of the musket pendulum, calculated by the mean recoil in each series of fires with similar powder and ball; this furnishes an easy method of comparing the velocities and the recoils produced by the same charge of different kinds of powder.

#### WITH THE MUSKET PENDULUM.

### May 10th, 1844.

The first experiments were made with the ballistic pendulum, before the musket pendulum was suspended. It was intended first to compare the effects of the flint and percussion locks in firing the charge. For this purpose a musket was altered to the percussion system, by substituting a hammer for the cock, and by screwing a cone into the top of the barrel; the hole cut for the cone being plugged with a solid screw of the same form as that of the cone, and the original vent remaining open, the musket was first fired with a flint lock.

In the first arrangement of the ballistic pendulum the lead in the core of the block weighed  $9\frac{1}{2}$  lbs., and instead of the wooden block afterwards adopted to receive the ball, a paper case filled with sand was used. The whole weight of the pendulum was 59.5 lbs.

The dies for compressing the balls had not been perfected; the balls first made were therefore not quite spherical, and they were too large, their mean diameter being about 0.6415 in., and their mean weight 400 grs.

'The musket was loaded by introducing the charge of powder in the manner before described; on this was placed a circular wad made of a single thickness of cannon cartridge paper, and a similar wad was inserted over the ball; the object of these wads being merely to keep the powder and ball in place.

The diameter of the bore of the musket used is 0.69 in.

#### WITH THE MUSKET PENDULUM.

By comparing the results of these first experiments with those obtained by means of the same instrument in France, as marked on the packages of gunpowder received from that country, (see page 10,) it is evident that the velocities of the ball are much too low for the charges used, and not knowing that the French instructions for the use of the pendulums were in possession of Messrs. Dupont, from whom the drawings were obtained, I proceeded to make experiments, for the purpose of ascertaining the cause of these discrepancies.

Before trying the musket pendulum, and changing the manner of loading the musket, I made experiments on various modes of forming the core of the ballistic pendulum block, in order to determine the most advantageous arrangement for that purpose, and to ascertain if any marked variation in the effect of the blow could be traced to the formation of the core, or to changes in the weight of the pendulum.

### May 13th, 1844.

Three different arrangements for the core of the pendulum block were tried to-day :

1st. A paper case filled with sand, as in the preceding experiments, with a leaden block behind it.

2nd. A block of wood in place of the sand case.

3d. A core formed of a conical block of lead, faced with a plate of iron.

With each of these cores the weight of the pendulum was made to remain the same as before.

The firing was with a new flint lock musket, except the two rounds noted "vith percussion lock," for which the altered musket was used.

The balls in all these preliminary experiments were of the same kind as those used on the 11th inst., being of the diam. of 0.641 in.; weight 399 grs.

The wads were also the same as in the previous experiments. The charge of 77 grains was used for the sporting powder, because it is marked as the proof charge, on the package of French sporting powder, which gives to the musket ball, with that charge, a velocity of 1306 feet.

#### WITH THE MUSKET PENDULUM.

# May 14th, 1844.

In order too ascertain whether the lateral vibration of the pendulum frame, occasioned by its want of stiffness, produced any sensible error in the result of the experiments, the frame was well stiffened with light wooden braces, which increased its weight about 2 lbs. The centre of gravity and centre of oscillation having been again determined, three rounds were fired with the charge of 77 grs. of powder, G. 6, when it was found that the mean velocity of the ball was 971 ft., not very different from the result of previous trials; the braces were therefore removed, and the pendulum was used in its first condition.

# May 16th, 1844.

The condition of the pendulum was again changed by attaching a supplemental weight to the lower side of the block, so as to bring the centre of oscillation to coincide with the point of impact of the ball; the weight of the pendulum was then 82.58, lbs. and its centre of gravity was 65.45 in. from the knife edges. Five rounds were fired from a percussion musket, with the pendulum in its original condition, and five more with the supplemental weight attached to it.

# May 17th, 1844.

The next experiments were made with a reduced weight in the core of the block :

1st. A wooden core with an iron plate on the front end, and a sand case over it—Weight of pendulum 51.54 lbs.

2d. With a block of lead lighter than the one heretofore used, and a sand case over it—Weight 55.3 lbs.

As the weight of 82 lbs., which is required in order to bring the centre of oscillation of the pendulum to coincide with the usual point of impact of the ball, appears to be disproportionate to the momentum of the ball, it was determined to adopt, for the present, the last mentioned method of forming the core of the pendulum block, viz: that which makes the weight of the pendulum 55.3 lbs.

# May 20th, 1844.

The musket pendulum was to-day suspended and adjusted, preparatory to making experiments on the proper mode of loading the musket barrel.

The first trials were made with the same mode of loading as has been heretofore used, the wads being cut out of thin paper.

# Mary 24th, 1844.

The increased velocity obtained by simply wrapping the ball in cartridge paper, led to further trials on different kinds of wadding. Three kinds were tried to day:

1. Circular felt wads, cut from the body of a hat, weight 3 grs.

2. Circular pasteboard wads, about  $\frac{1}{10}$  th in. thick, " 8 grs.

3. Rectangles of cartridge paper,  $3 \text{ in.} \times 4.5 \text{ in.}$  "9 grs.

In using the wadding of cartridge paper, (except in two instances specially noted.) the balls were wrapped in the cartridge papers, which were then crumpled into a wad inserted next to the powder.

\* Wad turned edgewise.

From these experiments it appears that the discrepancies between the former results and those of the French experiments, are occasioned by differences in the mode of wadding the charge, and that the most advantageous wads are those made of thick pasteboard, or of the paper of the cartridges commonly used in service.

# May 27th, 1844.

The conclusions drawn from the foregoing experiments are confirmed by information received on the 25th inst. from Mr. A. Dupont, who has a copy of the French instructions for the proof of gunpowder by the ballistic pendulum. It appears that, in proving *sporting* powder, the charge is  $\vartheta$  grammes, (77.17 grs.,) and that a pasteboard wad is put on the powder and another on the ball. For *war* powder, the charge is 10 grammes, (154.33 grs.) and the ball is wrapped in cartridge paper, which forms the wad, as in my experiments of the 24th inst.; but the ball is placed next to the powder and the wad on top.

Having, in the mean time, procured some circular wads of a very neat kind, such as are used by sportsmen, I made to-day some further trials to compare the effects of different kinds of wads.

The sportsmen's wads referred to are "Baldwin's elastic indented wadding," made in Birmingham, England; they are cut from a soft, spongy kind of pasteboard, a little more than  $\frac{1}{10}$ th of an inch thick. Those tried to-day were No. 14, which are a little too large for the musket. The mean weight of 253 of these wads is 5.127 grs.

The cartridge papers were 4.5 in.  $\times$  3.5 in., weighing 12.82 grs.; they were still inserted with the ball uppermost. The pasteboard and felt wads were of the same kind as on the 24th.

Heretofore the charge has been rammed with a hickory ramrod, in the usual manner. To produce greater uniformity in this respect, I now adopted the method described in the French instructions; letting fall on the charge, from the height of 6 in., a ramrod weighing 1.5 lb.

The ball was fired into a case filled with sand, as in the former experiments.

# May 29th, 1844.

In order to try a ballistic pendulum much lighter than the one heretofore used, the bronze block was removed, and a sheet iron case substituted for it; beneath this case, which was to contain the sand core, adjusting weights were attached to the suspension frame, so as to bring the centre of oscillation to coincide nearly with the point of impact of the ball.

The whole weight of the pendulum was 47.27 lbs. Distance of centre of gravity from knife edges, 62.33 in. Distance of centre of oscillation from knife edges, 79.06 in. The pendulum was tried with the following results:

| 1   | POW               | DER.                | VIBRA                                   | T10N.                                                       | y the<br>lulum.                       | in the second second                                                                                      |

At the fourth round, some of the rivets which held the sheet iron case gave way, and the apparatus could be no longer used without repair; but as the indications of the two pendulums corresponded with each other, and with the results of former trials, it was concluded that the inertia of the pendulum, in its previous state, is not too great for the force of the ball; further trials with the lighter pendulum were therefore considered unnecessary, and the apparatus was restored to its original form.

# May 31st and June 1st, 1844.

Wishing to avoid the inconvenience of renewing the leaden cores which are used to receive the impact of the ball, in the French arrangement of the pendulum, and the further incon-

136

venience resulting from the fragments of lead which must be driven off against the sides of the pendulum block and against the face plate, I made some comparative trials of these leaden cores and of the wooden and sand cores before employed. In order to increase the resistance of the cores of oak wood, they were turned across the grain ; other cores of cypress wood, very light and dry, were also tried.

The dies for making the balls by compression having been well adjusted, a large number of balls have been prepared, of the diam. of 0.64 in.; mean weight 397.5 grs. These balls will be used in the future experiments, when not otherwise mentioned.

The following is a tabular view of the mean results of the experiments in which cartridge paper wads were used:

From this table, it appears that the indications of the ballistic pendulum are not sensibly affected by the kind of core used for the pendulum block, since the velocities of the ball, by that pendulum, follow very nearly the same order with the corresponding recoils of the musket pendulum; thus showing that the cause of variation is in the force with which the ball is propelled.

The cypress core affords too little resistance to the ball, which passes through it with such force as to indent the iron plate behind it.

The oak core, turned across the grain of the wood, causes a deviation in the course of the ball after it enters the pendulum block. As the wooden cores are the neatest and most convenient for use, it was determined to adopt that arrangement in the future experiments, and the pendulums were finally adjusted in the manner pointed out in the general description of them; the cores being turned out of seasoned hickory, and placed with the end of the grain towards the musket.

# June 3d, 1844.

Preparatory to determining the proper charge for the proof of gunpowder with the musket pendulum, the following trials were made with a musket altered to percussion:

1st. Firing 25 rounds, (at the rate of 2 rounds in a minute,) with a charge of 130 grains of powder, A. 4. The barrel became exceedingly heated, and the recoil was too.great to be borne without serious inconvenience.

2nd. 11 rounds with 120 grs. of powder taken from old musket cartridges, which have been made probably since 1816. Recoil not too great.

3d. 5 rounds with the cartridges from which the powder just mentioned was taken; they contain about 160 grs. Recoil much too great.

4th. 10 rounds with 120 grs. of powder, A. 4. The recoil with this charge is inconveniently great, being probably increased by the foul condition of the barrel. At 400 yards, the balls pass through a pine board 1 in. thick, and are flattened against a brick wall. The cartridge for the flint musket containing 130 grs., the charge of 120 grs. may be regarded as the present musket charge, exclusive of priming.

These 51 rounds were fired without cleaning the barrel, and only one percussion cap exploded without firing the charge, . although when the breech screw was taken out there was found

in the bottom of the barrel a hard cake of dirt, which, as subsequent trials showed, was produced almost entirely by the powder from old cartridges.

As it is obvious that the charge of the percussion musket cannot exceed 120 grs., and will probably have to be less than that, and as the effect of 120 grs. of our usual quality of musket powder appears to be sufficiently great for service, it was determined to adopt that charge for the experiments to be made in comparing different kinds of powder by means of the musket pendulum.

# June 5th, 1844.

The comparative trials of the flint and percussion muskets were now resumed. For this purpose the musket pendulum was dismounted, and the altered musket used on the 10th and 11th of May was again placed between wooden clamps, in a bench vice, by which it was held steadily in a proper direction for firing horizontally at the centre of the pendulum block. After firing ten rounds with the percussion lock, the vent in the cone of this musket was slightly enlarged, to the size of a common vent for a flint lock, and the piece was fired by means of a strand of quick match.

The percussion caps were English, and such as are used for the military service; the charge of powder was 120 grains; the rnusket was washed at every fifth round.

Experiments with musket ballistic pendulum, June 5th, 1844.

From these experiments it would appear that the increase of force; from the use of the percussion cap, is not so great as to authorize any reduction of the charge on that account alone.

harge of powder 120 grs.; diameter of ball 0.64 in.; weight 397.5 grs.; wad of cartridge paper 3 in.  $\times$  4.5 in., weighing 10.8 grs.; point struck 79 in. when not otherwise specified.

\* Face clamp of pendulum block fell off. † Wads struck the pendulum.

٠

The object of the experiments on the 5th July, was to compare the force of balls of diminished windage with that of the common musket balls. The large balls were made by compression, like the others, but they were not as accurate in their form; their mean weight was 414 grs., or very nearly 17 to 1 lb.; those selected for the experiments did not differ in weight more than  $\frac{1}{16}$  ths of a grain.

With these balls the paper wads were often carried into the pendulum block; but as it was not easy to estimate the weight of that part of the wad which struck the pendulum, no account has been taken of it in computing the velocity of the ball.

The falling off of the face clamp, in the experiments on the 5th, was caused by the reaction of a new leaden block in the core, which at first did not fit perfectly in its place, and therefore slipped, in the recoil of the pendulum; for this reason these experiments were repeated on the Sth, to verify the results.

In order to ascertain whether it would be practicable to use, in ordinary service, balls of the large size tried on the 5th, 100 rounds were fired from a musket altered to percussion, with a charge of 120 grs. of powder, A. 4.

The bore of this musket was 0.689 in. diameter, being a little under the regulation size of 0.69 in. The 100 rounds were fired without cleaning the barrel, which was cooled after every 20 rounds; the balls were wrapped, as usual, in cattridge papers, and no difficulty was experienced in loading the musket at any time.

COMPARATIVE TRIALS OF VARIOUS SMALL ARMS

Chamber included.

The balls for these arms were cast in the mould for Hall's carbine; they were nearly of the true diameter 0.525 in., and their average weight was 219 grs., or 32 to the pound.

For the arms loading at the breech, the balls were used naked. For the cadet's musket, they were wrapped in rifle cartridge papers, and the musket was loaded in the same manner as the pendulum musket barrel. The mean weight of the paper wads was 8.4 grs.

For the common rifle, the balls were wrapped in greased patches, the mean weight of which was 3.4 grs.; they were easily inserted with the rifle ramrod, and did not fit the bore quite as closely as balls prepared for ordinary service with the rifle. The patch was always carried with the ball into the pendulum block, and the weight of the patched ball is therefore used in computing the velocity.

The arms were held in a vice, to be fired at the pendulum block.

Rifle powder, A. 5, was used in these experiments. The chamber of Hall's rifle holds about 75 grains of powder, with the ball; that of Hall's carbine holds 100 grains. With 70 grains in the chamber of Jenks's carbine, the breech plug requires some force to bring it up to its place, and the powder is consequently compressed against the ball.

# WITH VARIOUS SMALL ARMS.

The paper used for wrapping the balls of 0.65 in. happened to be rather thicker than usual; weight of wad 13.25 grains.

The balls, it will be seen, are a little reduced in size and weight from those used on the 5th; they are also more nearly spherical.

In order to test further the practicability of using, in ordinary service, the balls with diminished windage, Major Symington, the commanding officer of the Arsenal, caused the following trials to be made with balls similar to those of 0.65 in. diameter used in the experiments of the 17th instant.

Two muskets, of the smallest size of bore, were altered to percussion by inserting a cone in the top of the barrel, and adapting a hammer to the lock; each of them was fired 1000 rounds, as follows:

# December 13th, 1844.

#### COMPARATIVE EXPERIMENTS IN FIRING WITH MATCH AND WITH A PERCUSSION LOCK.

The musket selected for to-day's experiments is a new Springfield Armory percussion musket, which was held in a vice, as in former trials. The diameter of the bore of this musket (by the gauge used for the balls) is 0.688. The balls are similar to those used yesterday.

In order to give the full force of the percussion powder, caps recently made at this Arsenal, and not varnished, were used; these caps contain about  $\frac{6}{10}$  of a grain of percussion powder.

\* Charge rammed hard.

At the last round, the quick match failed, in repeated trials, <sup>-</sup> to fire the charge, which was rammed several times, without

success, to force the powder up into the cone; it was then fired with a percussion cap.

Experiments were also made to-day with the new model percussion pistol, of rifle calibre. Diameter of bore 0.54.

To ascertain the force of the charge, the ball was fired into the pendulum, the pistol being held 2 feet from the face of the block, in order that the ball should strike near the centre; in that position, the vibration of the pendulum was sensibly increased by the blast and by the wad striking it. To ascertain the correction to be made for this effect, several blank charges were fired, and it was found that the vibration caused by the charge, without a wad, was 12'; with a wad 20'. The latter quantity is therefore deducted from the arc of vibration, to obtain that which is due to the ball alone.

The balls with the paper fit close in the bore.

In firing the pistol, with various charges, it was found that although 40 grains of the powder used in the above experiments may be fired without serious inconvenience, 30 grains

form a sufficient charge to be used with ease to the hand; with this charge, the ball retains great force after passing through a 1-in. board at 40 yards. Other trials were made on the 19th, with the same charge, when two balls, in five shots, were placed, at 80 yards, in a target 6 ft.  $\times$  3 ft.; the balls passed through a board 1 in. thick, and ranged to a considerable distance beyond the target.

# December 19th, 1844.

Other comparative experiments were made to-day, on the effect of firing the musket with a match and with a percussion lock.

For these trials, a musket of the *largest* bore was selected from a box of 20 new percussion muskets; diameter of the bore 0.694 in.; it was held in a vice, as before, to be fired. The caps used to-day were of the same kind as those used on the 13th, except that they were varnished.

Experiments were also made with a new percussion rifle. The balls were wrapped in greased patches of linen cambric; but little force was required to ram them down with the rod belonging to the rifle. As the patch went with the ball into the pendulum block, its weight is included, in computing the velocity of the ball.

160

The charge of 80 grains for the rifle was tried by firing at a target, 12 rounds at 130 yds., and 12 rounds at 200 yards distance; the accuracy of fire was satisfactory, and the force of this charge is, obviously, abundantly sufficient for the rifle. It can be used without the slightest inconvenience from the recoil.

With the musket, 20 rounds were fired with 110 grains of the musket powder X. p. 4, and balls of 0.65 in. The recoil with this charge can be borne without serious inconvenience, but it is considered that no greater charge of such powder can be advantageously used with these balls.

It should be remarked, that on account of unavoidable imperfections in the temporary arrangements for making balls by compression, to be used in these experiments, the balls are not quite uniform in size; the variation in the balls said to be of 0.65 in. diameter, is indicated by the difference of weight between those used in the late experiments, and those which were tried in July, the former being smaller and lighter than the latter.

#### January 14th to 16th, 1845.

Some experiments were made on the effect of firing the musket with the charge of 110 grains of musket powder X.p. 4., and balls of 0.04 in. windage; by ascertaining the depression of the ball, at different distances, when fired horizontally.

For this purpose the barrel of the new percussion musket was inserted in a heavy stock attached to a strong frame, in such a manner that it could either be placed level, or at an elevation.

A target was placed successively at different distances from the musket, and at each distance, a horizontal line was traced on it at the height of the axis of the barrel, which was about  $3\frac{1}{2}$  ft. above the general level of the ground. The target was 8 ft. long and 5 ft. high.

The musket barrel was loaded in the same manner as for the pendulum experiments, and it was fired with quick match.

The results of the experiments are given in the following table:

WITH THE MUSKET.

# IV. EXPERIMENTS WITH THE 1-POUNDER GUN PENDULUM.

The object of these experiments was to compare the indications of the strength of powder by a 1-pounder gun, with those furnished by the 24-pounder gun, in order to determine whether a gun of the former calibre can be made to serve the purpose of an eprouvette for cannon powder.

The gun was made for the purpose, of cast iron, and it is suspended, by means of an iron frame and shaft, similar, in many respects, to those of the heavy gun pendulum. The knife edges of the shaft rest in V's of cast steel attached to the top of a wooden frame, which is braced in such a manner as to be perfectly steady; to this frame is secured a brass limb, on which a slider is moved by the index of the pendulum; the limb is divided into spaces of 10 minutes which are subdivided into minutes by a vernier on the slider; the radius of the graduated arc is 67.3 in.

| The diameter of the bore of the gun is  | -     | - | - | <b>2.0</b> | in. |
|-----------------------------------------|-------|---|---|------------|-----|
| Diameter of the vent                    | -     | - | - | 0.1        | in. |
| Length of bore, including hemispherical | botto | m | - | 32.5       | in. |

The weight of the gun is about 300 lbs., and of the frame 130 lbs.; but, by some preliminary experiments, it was found that with this weight the recoil produced by a charge of  $\frac{1}{4}$  lb. of the strongest powder was more than 20°, within which limit it was thought advisable to reduce the recoil; a supplementary weight was therefore attached to the gun, in such a manner as to bring its axis into a horizontal position when the pendulum was at rest. When finally adjusted, it was found that:

The weight of the pendulum - p'=542.5 lbs. Distance of centre of gravity from knife edges g'=75.5 in. Distance of axis of gun from do. i'=84.0 in. Distance of centre of oscillation from do. o'=83.69 in. Hence.  $2p'g'\sqrt{G_{CC}}$ 

Log. 
$$\frac{2p \ g \ \sqrt{G} \ o'}{12 \ i'} = 4.1644178$$

# WITH THE 1-POUNDER GUN PENDULUM.

A supply of 1-pounder cast iron balls was procured from the Columbia foundry, near Georgetown; these balls are smooth and nearly accurate in form; they are all between 1.93 in. and 1.96 in. diameter, and by a judicious selection of the iron, they were made to weigh almost exactly 1 lb. For the present experiments, balls were selected between 1.955 in. and 1.96 in. diameter, (true diameter, say 1.9525 in.) and between 0.99 lb. and 1.01 lb. in weight, none of the balls being so light as the former weight, and none so heavy as the latter. The journal of experiments shows the actual weight of each ball used, but as the variations are very small, the mean weight 1.0013 lb. has been used for all of them, in the calculation of the results, and therefore the particular weight of each ball is not here given.

The bags for the powder were made of musket cartridge paper, on a former 1.85 in. diameter, having a hemispherical bottom to fit the bore of the gun; their mean weight is 0.0038 lb. When filled, the mouth is neatly closed by folding down the surplus paper on the powder.

The balls are held in place in the gun by grommets made of a small strand of packing yarn formed into a ring of the full size of the bore; these grommets are readily inserted by means of a rammer, the head of which is hollowed out, to go partly over the ball. The mean weight of the grommets is 0.0045 lb.

The gun being charged, the cartridge is pricked, and the charge fired by means of a strand of quick match.

The gun is cleaned with a cylindrical wire brush, made of a piece of cotton card nailed on a staff; this brush scrapes off the dirt and removes the bottom of the cartridge bag which always remains in the gun after the discharge; the bore is then wiped with a sponge, or a sort of mop made of rags, and after 3 rounds it is washed.

As the force of the charge, or the velocity of the ball, is to

be determined by the recoil of the gun pendulum only, the balls are fired into a long box filled with sand, the depth of which, in the direction of the line of fire, is 3 feet. With the charge of 4 oz., which was used in these experiments, the balls penetrated nearly through the sand and were taken out uninjured, from near the back part of the box, which was made to open at top for the convenience of recovering the balls. The box rested on rollers and by moving it a few inches endwise after each shot, the balls were prevented from striking together; they were a little scratched by the sand, but not sensibly altered in form, size or weight, and they might no doubt be used several times over, without impairing the accuracy of the results.

The apparatus was placed in a large building, where it was served with perfect convenience, and all the arrangements were found well adapted to the use of such a pendulum. The frame has sufficient strength and stiffness, and the motion of the pendulum is very slightly impeded by the friction of the knife edges, as will appear from the following observations, made in determining the centre of oscillation : the loss of motion in 500 oscillations, beginning in an arc of  $2^\circ$ , was 40 minutes; in 500 oscillations, beginning in 'an arc of  $1^\circ 20'$ , the loss was 20 minutes.

The velocity of the ball is computed by the formula heretofore given for the heavy gun pendulum. (Page 32.)

$$v' = \frac{\frac{2 \sin \frac{1}{2} A' \times p' g' \sqrt{G o'}}{i'} - Nc}{\frac{b' \frac{D^2}{d^2} + \frac{1}{2} c'}}$$

the notation being the same as before.

In accordance with the remarks made, in the discussion of this formula, relative to the decrease in the value to be assigned to the quantity N, as the charge and the calibre of the piece are diminished, I have here assumed for N the value of 1400 feet.

166

Ι

By assigning to the other elements of the formula their constant mean values as above stated, we have, for computing the results of the following experiments:

b', the weight of the ball and wad = 1.0013 lb.+0.0045 lb. = 1.0058 lb.

c', the weight of powder and bag = 0.25 lb.+0.0038 lb. = 0.2538 lb.

**D**, diameter of the bore = 2 in.

d, diameter of the ball = 1.9525 in.

c, weight of the powder = 0.25 lb.

and the formula for the velocity of the ball, in feet, becomes:  $\sin \frac{1}{2} A' \times 14602.2 - 350$  in  $1 A' \times 19251$  7 206 1

$$v = \frac{1}{1.1822} = \sin \frac{1}{2} A' \times 12351.7 - 296.1$$

which furnishes a very easy method of computing the velocity, when the weight and diameter of the balls are not different from those above stated. By selecting, for any set of experiments, balls which shall be nearly uniform in size and weight, though differing from the above, the same form may be always given to the expression for the velocity.

The greatest error which could arise from the use of these mean values, in computing the results of the present experiments, is about 14.5 ft. in a velocity of 1440 feet, or  $\frac{1}{100}$  th part; but this is on the supposition that the largest ball may be the lightest, or vice versa, a case which would rarely occur, if ever; this error too is, in a great measure, compensated by the fact that the formula, in this state, assigns too high a velocity to the heavier balls and too low a velocity to the lighter ones, so that a correction of the results to a uniform standard weight of ball is already made.

The greatest actual error, in these results, after making the correction for difference of weight in the balls, is found to be 6 feet.

The values of the term  $\frac{2 p' g' \sqrt{G o'}}{12 i'} \times \sin \frac{1}{2} A'$ , heretofore denominated the moment of the gun pendulum, have been computed for these experiments and are given in the tables.

#### V. EXPERIMENTS WITH AN 8-INCH MORTAR.

The mortar used in these experiments was a new, light 8-inch iron mortar, with a Gomer chamber; its principal dimensions are as follows:

|          |                                   |                                            | Inches.                                            |                                                                    |

|          | ve of c<br>at botto<br>amber<br>- | ve of chambe<br>at bottom of sl<br>amber - | ve of chamber -<br>at bottom of shell<br>amber<br> | 8.02<br>ve of chamber - 12.<br>at bottom of shell 6.08<br>amber 4. |

The mortar was mounted on a solid cast iron bed, which was placed on a horizontal platform, 6 feet square, formed of timbers 8 in. square. It was pointed at  $45^{\circ}$  elevation.

The shells are 1.4 in. thick; they were filled with sand, so as to weigh 48 lbs. 'These shells were selected with gauges of the diameters 7.8 in. and 7.85 in.; they are therefore considered to be of a mean diameter of 7.83 in., having 0.19 in. windage.

The charge of powder was 12 oz.; it was contained in paper cartridge bags, and fired with a strand of quick match.

'The ground on which the shells fell was dry and hard, and they did not bury themselves; penetrating generally but little more than half a diameter.

The times of flight were observed by means of a very delicate *michronometer*, (made by Mr. Montandon, of Washington,) which marks the sixtieth part of a second, and which was used in many of these experiments, for noting small portions of time.

The mortar is of iron, cast with a sole which is fitted into a bed plate, in such a manner as to prevent recoil; the bed plate is secured to a platform established on a foundation of solid masonry. The mortar is fixed at an elevation of  $45^{\circ}$ .

In these experiments, eprouvette No. 16 was used, always with the same ball, No. 4, belonging to that mortar. After trying each kind of powder, the mortar was washed and then dried with a blowing charge; the first charge with ball generally giving a low range, the mean result of the proof is deduced in almost all the cases from the 2nd and 3d charges; but the relative force of the different samples would have appeared very nearly the same if the mean of the three rounds had been taken.

The dimensions of the chamber of the mortar being calculated for powder of medium density, 1 oz. of the lighter kinds, the gravimetric density of which is below 830, is not easily contained in the chamber, and has to be settled in by rocking the mortar on its bed, whilst it is held in a vertical position. On the other hand, 1 oz. of the heavier kinds of powder, of the gravimetric density of 930, leaves a considerable vacant space between the powder and the ball.

#### WITH THE FRENCH MORTAR EPROUVETTE.

## VII. EXPERIMENTS WITH THE FRENCH MORTAR EPROUVETTE.

| The principal dimer       | nsion | s of th | ne mort | ar a | re as t | follows :   |
|---------------------------|-------|---------|---------|------|---------|-------------|
| Diameter of bore -        | -     | -       | •       | -    | -       | 7.53 in.    |
| Length of bore, exclusion | sive  | of cha  | amber   | -    | -       | 9.48        |
| Diameter of chamber       | -     | -       | -       | -    | -       | 1.95        |
| Length of chamber         | -     | -       | :       | -    | -       | 2.58        |
| Diameter of vent -        | -     | -       | -       | -    | -       | 0.13        |
| Weight of mortar -        | -     | -       | -       | -    | -       | 257 lbs.    |
| Windage of ball -         | -     | -       | -       | -    | -       | 0.0666 in.  |
| Weight of ball -          | -     | -       | -       | -    | -       | 64.6 lbs.   |
| Charge of powder 0        | 2     | mmos    |         | 20 m | ·       | l or neerly |

Charge of powder, 92 grammes = 1420 grs.  $= 3\frac{1}{4}$  oz. nearly. The mortar is of bronze, cast with a sole which is bolted to a wooden bed. It is placed on a level platform of timber, and is allowed to recoil freely. It is fired at an elevation of  $45^{\circ}$ .

The service of the eprouvette was conducted according to the instructions in the Aide Mémoire d'Artillerie, and the mean results are taken in the same manner as with the U.S. eprouvette.

The mortar and globe used in these experiments were received from the French War Department, and have been adjusted at the "Atelier de précision" in Paris. The globe is of iron; but although the ground on which it fell was free from stones, its great weight causes it to be much bruised, even by small pebbles.

## VII. EXPERIMENTS WITH THE ENGLISH HALF-POUND GUN EPROUVETTE.

This eprouvette consists of a brass gun suspended as a pendulum; it is fired without ball or wad over the powder, and the force of the charge is estimated by the extent of recoil expressed in degrees and tenths.

| The diameter of the bore of the gun is -        | - | 1.75 in. |
|-------------------------------------------------|---|----------|
| Length of bore                                  | - | 27.2     |
| Distance from the axis of bore to axis of shaft | - | 31.45    |
| Charge for proof of powder                      | - | 2 oz.    |

The journals of the suspension shaft are cylindrical, 0.5 in. in diameter and 1 in. long. The friction of these journals is such, that when the pendulum is set in motion in an arc of  $10^{\circ}$ , it does not make more than 80 vibrations before the extent of them becomes insensible.

The instrument used in these experiments was received from the British Ordnance Department. The service of the eprouvette was conducted according to the instructions contained in Griffith's Artillerist's Manual. When, by repeated firings, the gun became unduly heated, it was filled with water and allowed to cool; after the trial of each kind of powder, it was washed, and dried with a blowing charge.

|                                                       | Kind of                                              | VIBRA                                                      | TION OF                                                         | F EPROU                                                     | VETTE.                                                               |                                                                                           |

Experiments with the English half-pound gun eprouvette-(Continued.)

In firing a charge of the powder T. a sheet of thick paper, held about 4 ft. in front of the muzzle of the gun, was perforated as if with a charge of small shot; with a charge of French sporting powder, the paper was blown into fragments, but was scarcely discolored.

#### WITH ALGER'S EPROUVETTE.

#### IX. EXPERIMENTS WITH ALGER'S EPROUVETTE.

This eprouvette, made by Mr. Alger, of the South Boston foundry, is an iron mortar, or rather a short howitzer, the chamber of which is intended to hold *half an ounce* of powder. Its principal dimensions are as follows:

| Diameter of bore -     | -     | -          | -      | -      | -    | 6 in.   |
|------------------------|-------|------------|--------|--------|------|---------|
| Length of bore, includ | ing h | emis       | pheric | al bot | tom, | 27      |
| Diameter of chamber    | -     |            |        |        |      | 1.5     |
| Depth of do.           | 4     |            | -      | +      | -    | 0.7     |
| Diameter of vent -     |       | 1.         |        | -      | -    | 0.1     |
| Weight of ball -       | - *1  | -          |        | niet.  | -    | 30 lbs. |
| Charge of powder       |       | -          | -      | (-)    |      | 1 oz.   |
| mi · · · · · ·         | 1     | the second |        | 1      |      | e 1.    |

The piece is furnished with trunnions, by means of which it is supported on a cast iron bed with high cheeks, at an elevation of  $60^{\circ}$ .

The windage of the ball is scarcely appreciable, being just sufficient to admit it into the bore.

The chamber is formed in a breech plug of wrought iron, which is screwed into the bottom of the bore. This plug is 2.6 in. in diameter; it is perforated in the axis, to receive a moveable plunger 0.35 in. in diameter, which contains the vent. At right angles to the axis of this vent, which is not bored through the whole length of the plunger, holes are bored through the plunger and through a projecting part of the breech of the gun, which holes correspond with each other when the inner end of the plunger is flush with the bottom of the chamber; hence a priming tube inserted in the exterior part of the vent communicates its fire to the charge, but as soon as the charge explodes, the plunger recoils and the communication with the vent in the gun is cut off, so that no escape of gas takes place from the vent. The recoil of the plunger is

checked, at the proper distance, by its striking against the bed of the piece. Although the distance from the exterior vent to the bottom of the chamber, or the length of the vent in the plunger, is 4.25 in., the fire from the tube rarely fails to ignite the charge in the gun.

The powder is contained in cylinders of thin paper made to fit the chamber, and closed at the top by discs of paper or pasteboard, of different thicknesses, according to the density of the powder, so that there may be no vacancy left between the cartridge and the ball. The bottom of the eartridge is pricked with a pin, before it is inserted in the chamber.

The eprouvette was established on a solid stone platform, on Dorchester point, near Boston; and as other business called me in that direction, I took with me samples of the powder to be tried, put up in close tin canisters. The cartridges were prepared, and the gun was served by the person who had been generally employed for that purpose, in other trials of the instrument.

The anomalies which will be remarked in the ranges with this eprouvette are attributed, in a great measure, to the small windage of the ball, in consequence of which a slight scratch, or a minute portion of dirt, which might adhere to the ball or the gun, notwithstanding great care in cleaning both, would keep the ball off from the mouth of the chamber and permit the escape of gas around it.

The experiments are considered worthy of record, because the arrangements of the eprouvette embrace several of the modifications which have been suggested, by writers on the subject, for improving the common mortar eprouvette: such as increasing the length of bore, reducing the windage, and closing the vent.

It does not appear that these modifications are of any value in correcting the inherent defects of the instrument.

#### X. EXPERIMENTS IN DETERMINING THE RELATIVE DENSI-TIES OF VARIOUS KINDS OF GUNPOWDER.

## Gravimetric densities.

The term gravimetric density is used to signify the weight of a given bulk of powder. It is here expressed by the weight of a cubic foot, in ounces.

The measure used for determining the gravimetric densities in these trials, is a cylindrical brass vessel 4.1625 in. in diameter and 8.464 in. high, containing, therefore, one fifteenth part of a cubic foot. Its capacity was adjusted by the weight of rain water which it should contain.

The powder is poured into it from a hopper in the form of a truncated pyramid, the smaller end of which has an opening about 1 in. in diameter, which is closed when necessary, by a sliding valve. This hopper is supported on a frame, so that its lower end is about 2 in. above the mouth of the powder measure; by withdrawing the valve, the powder is allowed to run until the measure becomes heaped, when it is carefully striked with a straight edge and weighed.

In determining the weight of the powder when it is settled, as in a cartridge, about one pound at a time was poured into the measure, which was shaken and the bottom struck carefully on a block of wood, until the powder nearly or quite ceased to settle.

The two trials with each kind of powder were, with very few exceptions, made with different parcels.

This method of determining the gravimetric density is the same as that practised at the English and French government powder works; except that in England the *gravimeter* is a vessel containing a cubic foot, (according to Braddock,) and in France it is a *litre*, which holds 61 cubic inches nearly.

## ON THE DENSITY OF GUNPOWDER.

# Table of gravimetric densities-(Continued.)

\* Powder dried in the sun.

.

.

## ON THE DENSITY OF GUNPOWDER.

## Specific gravities of several samples of powder.

Some experiments were tried in determining the specific gravity of gunpowder, by weighing it in water saturated with saltpetre, according to the method used in the French service, and described in the Ordnance Manual, page 153.

'The vessel used for this purpose, in the experiments of the 11th and 12th of September, 1843, was a glass bottle having a well fitted ground glass stopper. In the other experiments, there was used a straight glass jar, about 2.5 in. in diameter, and 7 in. deep, the top of which was ground true and covered with a plate of ground glass.

The following tabular statement exhibits the results of these trials :

| DATE.                                                            | Contents of glass                                                                                              | Kind<br>powder.                        |                                                                  | WEIGHT.                    |                          |                                                                         |                                      |  |  |  |

\*Four trials.

It will be observed, that notwithstanding the care which was taken to keep the saltpetre water in a state of saturation, there is a sensible variation in its density, the heavier portion being that from near the bottom of the vessel which contained it. This method of determining the specific gravity of gunpowder seems liable to inaccuracy from the above cause, and still more from the error which may be introduced by a slight change of temperature during the experiment, causing the solution to deposit some of its saltpetre, or else to take up some of that in the powder; another cause of error may be found in the difficulty of ascertaining when the moisture in the powder is expelled, so as not seriously to affect the results. By being poured into the saltpetre water, the powder is almost immediately reduced to the state of paste, from which it is not always easy to expel the air completely.

Owing to these circumstances, it appears to me that this method cannot give correct indications of the influence of different modes of manufacture, &c., on the density of gunpowder.

## ON THE DENSITY OF GUNPOWDER.

Having observed that gunpowder is not apparently altered by immersion in highly rectified alcohol, I made other experiments on the specific gravities of several kinds of powder, by weighing them under alcohol; using for this purpose the same glass jar that was used in the experiments with saltpetre water.

The results of these experiments are exhibited in the following table :

| DATE.                  | Contents of vessel.                                  | Kind of<br>powder.                            | Weight.                                                 | Specific<br>gravity.                         | REMARKS.                                   |

The powder for these trials was well dried in the sun, but some differences in the results are undoubtedly due to the difference in the degree of moisture left in the powder, as this would necessarily be greater in the large grains than in the

small. From the specific gravity of the alcohol it will be seen, that although not perfectly pure, it contains but a small proportion of water; the powder, dried after immersion, shewed slight traces of water, in the efflorescence of minute crystals of nitre on the surface of the grains. The principal difficulty in the use of this method of determining the specific gravity, or the absolute density of gunpowder, is that of expelling all the air from the interior of the grains; for this purpose it is necessary that the powder should remain a considerable time under the alcohol', and that it should be occasionally stirred, to let the air escape. Some of the above results are probably affected by this cause of error, which, for want of practice, I could not always avoid in these first experiments; but they are thought worthy to be recorded in this report for future reference and comparisons, and as affording near approximations to the true densities of the samples of powder tried.

The following statement shows the results obtained by direct measurement and weight of two pieces of mill cake, similar to that used in making powder G, which I have had in my possession since 1837, and which have been kept dry.

Number of grains of powder in a given weight-(Cont'd.)

## ON THE RELATIVE SIZES OF GRAIN OF GUNPOWDER. 195

The sizes of grain of some of the powders were compared by means of the standard gauges for gunpowder.

The diameters of the holes in the sieves which serve for powder gauges are nearly as follows:

| No. of sieve                          | - | - | 1           | 2            | 3           | 4         | 5         | 6     | 7    | 8     |

When one pound of powder is sifted by these gauges, not more than 1 oz. should remain on the largest gauge; not more than 3 oz. should pass through the smallest, and not more than half the remainder should pass through the medium gauge.

Of the *rifle powder* A. 5, when sifted in this way, too much remains on No. 6, whilst a due proportion passes through No. 8. It contains therefore too many large grains.

Of the *rifle powder* C. 5, much remains on No. 5, and a few grains even on No. 4; only a few grains pass through No. 8, and very little through No. 7. This powder is therefore altogether too coarse for rifle powder.

Of the English musket powder, all passes through No. 4,

very nearly all through No. 5,

and some portion through No. S.

Of the English rifle powder, all passes through No. 6, nearly all through No. 7,

and a due proportion thro' No. 8.

Of the musket powder X. p. 4, all passes through No. 4, much remains on No. 5, very little passes through No. 6. Of the rifle powder X. p. 5, a small proportion remains on No.6, and a like proportion passes

through No. 8.

## XII. EXPERIMENTS ON THE RELATIVE QUICKNESS OF BURN-ING OF DIFFERENT KINDS OF GUNPOWDER.

The quickness of the powder was tested by observing the time occupied in burning a train laid in an open groove. For this purpose, two semi-cylindrical grooves were cut in the opposite sides of a bar of iron, 40 ft. 4 in. long; the diameter of one groove is 0.8 in., that of the other 0.4 in., or one-fourth of the capacity of the first. The powder was laid in the grooves by means of a funnel with a sliding valve at the bottom, by which the escape of powder could be regulated; and the surface of the powder in the groove was levelled, when necessary, with a straight edge. The coarser kinds of powder cannot easily be laid smoothly or uniformly in the grooves, but the circumstances are nearly equal, in cases where the size of grain of different samples is the same.

The quantity of powder which the grooves will contain was ascertained, for three samples, as follows:

| <br>Kind of powder. | In the large<br>groove. | In the small groove. |  |
|---------------------|-------------------------|----------------------|--|
| A.                  | Lbs.<br>2.46            | Lbs.<br>0.62         |  |
| F. 1                | 2.14                    | 0.53                 |  |
| G. 6                | 3.21                    | 0.92                 |  |
| <br>1               |                         |                      |  |

For greater convenience, the iron bar was, at first, bent in the middle, so as to place the two parts parallel to each other, 7.5 in. apart; to prevent the flame from communicating across, from one part to the other, a partition of boards was placed between them, but as this precaution was not found to be always effectual, the bent part was cut off after the first experiments, and its place supplied by a straight piece of the

## ON THE QUICKNESS OF GUNPOWDER.

.

same length, making a straight bar 40 ft. 4 in. long, which was used in the experiments in July, 1844.

The bar containing the grooves was placed level, on trestles of a convenient height, and the experiments were made in a large building which could be closed on all sides, to prevent the wind from affecting the results.

The time of burning was observed by means of the michronometer before mentioned, which marks sixtieths of a second.

As the results of the experiments with the same kind of powder in the two grooves, and with samples of the same powder, differing but little in the size of grain, appeared to correspond well together, it was not thought necessary to verify them by a repetition of the experiments.

Experiments in burning trains of powder in the small groove.

•

## ON THE HYGROMETRIC TEST OF GUNPOWDER. 199

## XIII. COMPARATIVE HYGROMETRIC TEST OF DIFFERENT KINDS OF GUNPOWDER.

The first comparison of the relative quantities of moisture absorbed by different kinds of powder was made by exposing samples of them to the damp air of a vault. For this purpose the powders were dried in the sun, on the 2d September, 1843, at a temperature of about 125°; one pound of each kind was then placed in a shallow dish of glazed earthenware, about 10 in. diameter, and these samples were deposited in a vaulted cellar under one of the storehouses of the Arsenal. In order to observe the progressive increase of weight, or the rate of absorption of moisture, the weight of each dish, with its sample of powder, was ascertained by the small platform balance used for weighing charges in the ballistic experiments with heavy guns, and the increase of weight was determined by the same balance at intervals of six days; but it was found that, after the first six days, the apparent increase of weight was too small to be accurately indicated by this balance, and the results are therefore not here given. The total increase of weight was determined by means of the same balance with which the samples were first weighed; the powders were then again dried for several hours in the sun, and their weights determined, as a check on the operation.

The temperature of the air in the vault was observed every day at 9 A. M. and 3 P. M.; these two observations differed from each other only on the 11th and 12th of September, and then but 1°; a comparison of these observations with those in the Meteorological Register, for the same period, shows that, after the first seven days, the temperature of the air in the vault was generally above that of the external air:

Temperature of air in the vault, on the 4th September, 73°; 5th, 6th and 7th, 72°; 8th and 9th, 71°; 10th, 70°; 11th to 19th, 68°.

## ON THE HYGROMETRIC TEST OF GUNPOWDER. 201

Other comparisons of the hygrometric qualities of various samples of powder were made by exposing them to air saturated with moisture; according to the method laid down in the French regulations for the proof of powder.

For this purpose, a tub, about 25 in. diameter and 15 in. deep, was filled with water to the depth of 9 in. In it were placed three piles of bricks, the tops of which stood about an inch above the surface of the water, and on each of these piles was a shallow rectangular tin pan, 9 in.  $\times$  6 in., containing 1,500 grains of powder, which had been previously well dried in the sun. The powder was spread in a layer of uniform thickness of  $\frac{1}{10}$  inch. The tub was then closed with a tight cover of boards, having a circular stuffed leather pad nailed on it at the part which bears on the tub; this cover was pressed down by a heavy weight.

Four of these tubs were prepared, and they were placed in a room at the south end of the artillery storehouse at the Arsenal. This room is flagged with stone and has windows only in the upper part of the walls, but it was found to be warmer than would have been desired for this purpose. Two self-registering thermometers indicated the highest and lowest temperatures during the intervals between the several weighings of the samples of powder.

The first samples were placed in the tubs on the 27th June, 1844. The increase of weight was determined, the first and second times, by removing the powder from the pans; but, as the quantity of moisture increased, the removal of the powder without loss became impracticable, and the pans having been carefully weighed, the subsequent weighings of the powder were made without emptying them.

The three samples enclosed in braces respectively, in the following tabular statement, were placed in the same tub. After the first 24 hours there was no apparent change in any of the

# JOURNAL OF THE EXPERIMENTS

samples except in that of sporting powder G. 6, which was caked hard, but easily broken up again into grains.

The weights of the samples of powder dried were taken on the 8th July, after they had been exposed 5 hours to the sun.

.

#### ON THE HYGROMETRIC TEST OF GUNPOWDER. 203

The grain of all the powder is swollen and permanently increased in size; that of sample F. 1 less so than the others. A large proportion of nitre was separated, in drying, from the powder in which the efflorescence of nitre was very great, especially from samples A. 1 and G. 1. The powder G. 6, when broken up into grain, after drying, assumed a reddish brown color, being nearly that of the charcoal with which it was made.

July 9th, 1844. Twelve samples of other kinds of powder were exposed to the hygrometric test, in the same manner as the preceding. The quantity of powder in each was 1500 grains, as before, weighed after having been well dried in the sun.

The bottoms of the pans were scarcely covered by the 1500 grains of the coarse grained powders A. 0 and F. 0.

# Hygrometric test of gunpowder-(Continued.)

#### ON THE HYGROMETRIC TEST OF GUNFOWDER. 205

The last twelve samples of powder exposed to moisture were dried on the 23d and 24th July, by exposure to the sun, but the weather was not perfectly favorable for the purpose, as will be seen by the constant excess of weight over that of the original sample.

A sample of 1 lb. of the Waltham powder H, dried in the sun, from  $9\frac{1}{2}$  to  $11\frac{1}{2}$  A. M. on the 27th June, 1844, was found to weigh 0.99 lb., being a loss of 1 per cent.

Samples of 1 lb. each of powders a and A, dried in the sun, from 1 to  $2\frac{3}{4}$  P. M. on the 24th of July, 1844, were found to weigh each 0.993 lb., having lost about  $\frac{7}{16}$  ths of 1 per cent.

## Trial with the musket pendulum of powder dried after exposure to air saturated with moisture.

In order to form an idea of the relative effect of the exposure to moisture, on the strength of the different kinds of powder, they were proved by firing two rounds of each kind from the pendulum musket, with a charge of 120 grains and a ball of 0.64 in. diameter, as before.

on the hygrometric test of gunpowder. 297 ial of powder dried after exposure to moisture. (Continued.)

#### JOURNAL OF THE EXPERIMENTS.

### XIV. METEOROLOGICAL REGISTER.

This table is extracted from the Register kept at the Depôt of charts and instruments of the Navy Department, in Washington.

The barometric observations are reduced, by Schumacher's Tables, to the standard temperature of 32° Fahrenheit.

The thermometer in the sun is placed 4 feet from the ground.

The dew point was directly observed only at 9 A. M. and 3 P. M.; for other periods, it is deduced from the temperature of the wet bulb, by Apjohn's formula; the results (which are marked \*) were obtained by means of an ingenious graphical construction of the formula, prepared by Mr. S. W. Hall, of Philadelphia.

# PART SECOND.

Having, in the first part of this Report, presented a full narrative account of my experiments on gunpowder, with all the details which have an influence on the results of them, I now proceed to condense those results, under their appropriate heads, and to offer some remarks and suggestions which have occurred to me in the course of analyzing and comparing the facts developed by these experiments.

Whilst, therefore, the preceding part of the report affords the means for a minute examination of the circumstances attending each of the experiments, this second part will present the general results, in a convenient form for reference, to those who may desire to examine the grounds on which my deductions are based, or to pursue, further than I have done, the investigation of any of the subjects embraced in this course of experiments.

## I. OF THE DENSITY OF GUNPOWDER.

For the reasons given in the Journal of experiments, I do not place entire confidence in the result of my experiments in determining the *specific gravity* of gunpowder, and therefore no summary of them is here given.

It appears to me that by immersing gunpowder in any liquid sufficiently thin to penetrate all the pores of the grain, it must be in a great measure disintegrated, and thus we shall obtain not so much the specific gravity of the mixture which forms the powder, as the combined specific gravity of the ingredients

#### SUMMARY OF THE EXPERIMENTS

themselves; the results would consequently depend less on the intimacy of the mixture, than on the trituration of the ingredients, whether before or after being mixed together; for we know that the specific gravity of charcoal may be increased fourfold by trituration, and that sulphur, on the contrary, is rendered less dense by the same operation.

It is only in this way that I can explain the small increase of density which is apparently produced by long working or by great pressure; as in comparing the specific gravities (obtained by alcohol) of powders R. 15', R. 90' and G, which have been worked under the rollers 15 minutes,  $1\frac{1}{2}$  hours, and 4 hours respectively; or those of A. 4 and E. 5, the former not pressed except by the rollers, and the latter pressed exceedingly hard.

The determination of the gravimetric density of gunpowder offers an easy and useful practical method of ascertaining its relative density, when the comparison is made between powders of similar kind and size of grain. It will be seen by the journal of experiments, that, by conducting this operation with care, a very satisfactory uniformity may be obtained in the results of trials with the same powder, and I may further state that these results appear to agree very nearly with those obtained with similar powders in England and France. In mv remarks, therefore, on the subject of the densities of the different kinds of powder, I shall refer generally to the following table of gravimetric densities. In this table the densities of the several powders, loose and settled, are compared together, as affording some indication of the relative irregularities in the form of the grain, since the most angular and irregular grain will show the greatest difference of weight by settling. The weight of the powder thus settled in the gravimeter shows also the space which a given charge will occupy in a cartridge.

## ON THE DENSITY OF GUNPOWDER.

### ON THE QUICKNESS OF GUNPOWDER.

## **1M. RELATIVE QUICKNESS OF VARIOUS KINDS OF GUN-**POWDER.

# Table showing the relative time of burning of trains of gunpowder laid in open grooves.

The size of grain exerts necessarily a great influence on the rapidity of communication of the flame, as well as on the rapidity of combustion of the grains; and it seems that the greater quickness with which the small grains are consumed 28

.

#### SUMMARY OF THE EXPERIMENTS

does not always compensate for the impediment which the offer to the rapid communication of the flame through the whole mass. The point at which this compensation takes place appears to depend chiefly on the density of the powder -Thus, the quickness of the powder A decreases with the size of grain, until we reach the musket grain A. 4, when there is a decided increase of quickness; whilst the very dense powder E still diminishes in quickness when reduced to the size of rifle grain E.5. The quickness of the light and porous powder F is little affected by variations in the size of grain; but the combustion of this powder is impeded by the quantity of dust which adheres to the surface of unglazed powder of this low density and hardness. The effect of glazing in impeding the combustion of powder, when free from dust, is shown by comparing the quickness of samples K.1.r. and K. 1. g.; but this advantage of rough powder is more than compensated by its greater liability to be reduced to dust.

Thorough incorporation of the ingredients increases the quickness of burning, unless the density is too great; but there appears to be nothing gained in this respect by 24 hours' work, in the pounding mill, over 14 hours' work. The effect of different degrees of working in the rolling mill, on the quickness of burning, is seen by comparing the powders R, from which it would appear that the quickness increases with the quantity of working only to a very limited extent; in consequence, no doubt, of the concomitant increase of density.

The very fine grained sporting powder G. 6 being thoroughly incorporated, free from dust, and composed of angular grains, although highly glazed, far surpasses all the other kinds in quickness.

Among the cannon powders, the Waltham powder H occupies the first rank in this respect; but it must be observed that a fair comparison of the relative quickness of burning of diffe-

#### ON THE HYGROMETRIC TEST OF GUNPOWDER. 221

rent kinds of powder can be made in this way only by sifting them to a nearly uniform size of grain.

#### IV. HYGROMETRIC TEST OF GUNPOWDER.

Table showing the increase of weight in 1 lb. of various kinds of gunpowder exposed to the moist air of a cellar, from 2nd to 19th September, 1843.

The powders A and B were very slightly caked by this exposure to moisture; E more so, especially the finer grains E. 3 and E. 5; powders F were not at all caked; all the others were very much caked; the fine grained powder G. 6, became hard caked on the surface, after 6 days' exposure.

At the end of 11 days, and still more plainly after the 17 days' exposure, there could be discerned, with a lens, an efflorescence of the crystals of nitre on the surface of the grains of all the powders. This efflorescence was very slight indeed in the powders F, and the crystals were of a dirty yellowish color; in the other powders, the crystals were of a brilliant white. The efflorescence of nitre was slight on the powders **B** and **E**, but in considerable quantity on the remaining samples.

#### ON THE HYGROMETRIC TEST OF GUNPOWDER. 223

Remarks.—After 24 hours' exposure to air saturated with moisture, there was no apparent change in any of the powders except the fine grained, G. 6, which was caked hard, although it had absorbed less moisture than several of the other samples.

On the fourth day, the samples C and D were caked, and the grains softened; samples G. 1 and G. 6 were also caked, but the grains were hard and dry; samples A. 5, E. 5 and H, were slightly caked; the rest not at all so.

An efflorescence of nitre was discernible on all the samples except the following: K. 1. r., M. 1 A. 0 and F. 0; it was scarcely perceptible on samples F. 1 and K. 1. g., but very great on samples G. 1 and G. 6.

After 11 days' exposure the efflorescence of nitre appeared on the surface of all the powders; but it was still very inconsiderable on the powders F, K and A. 0, whilst most of the dense powders A, G, N, &c., were completely disintegrated by it, and lost a great portion of their saltpetre.

The powders C and D must not be compared, in this respect, with the other kinds; for in consequence of the impurity of the saltpetre in these powders, a great quantity of moisture is rapidly absorbed by them; the deliquescent salts in the nitre are dissolved, the grains become so moist as to hold in solution the nitre which becomes separated from the other components, and the powder is soon rendered completely unserviceable. In confirmation of this result I may refer to the fact reported to the Ordnance office in July, 1844, by the military storekeeper at Apalachicola Arsenal in Florida: that ninety barrels of cannon powder and forty-seven of musket powder, of the same kind as powder C, which were sent to that Arsenal in 1838, had become caked, so that the contents of each barrel appeared to be a solid mass; whilst all the rest of the powder in the magazine, (consisting chiefly of powder

#### SUMMARY OF THE EXPERIMENTS

A,) made and sent to the Arsenal at the same time, was in good order.

On comparing the effect of exposure to moisture on the other samples of powder, it appears that, in general, water is absorbed less rapidly, and in smaller quantity, by the more light and porous pounding mill powders, than by dense rolling mill powders; a similar effect of diminished density is observed in comparing the two powders, R. 15' and R. 90'. Not only is a smaller quantity of moisture absorbed by the less dense powders in the same time, but the absorption of an equal proportion of moisture is less injurious to them, and it is more readily and completely expelled by the same exposure to heat.

An exception to this remark occurs in the case of powder, such as E, the density and hardness of which are so great as to impair its combustibility and materially diminish its force, unless it is reduced to very minute grains, finer than those of rifle powder.

This fact, with regard to the relative quantity of moisture absorbed by light and by dense powder, is so different from the general impression on that subject, that I may be excused for mentioning that it is fully corroborated by the French experiments heretofore alluded to.

Owing to the influence of the temperature of the place of exposure on the quantity of moisture absorbed by the powder, the comparison of the results contained in the above tables can be accurately made only between the samples tested at the same time, and in the same manner.

Although charcoal is the chief absorbent ingredient in gunpowder, it is not perceived that the mere difference in the proportion of coal exercises such an influence on the absorption of moisture as to counterbalance other causes of variation. Of these, the size of grain is one of the most obvious; since, other circumstances being equal, the small grains, presenting

#### ON THE HYGROMETRIC TEST OF GUNPCWDER. 225

a greater surface in the same weight of powder, will absorb more moisture than the large grains, or rather, will absorb it more rapidly; but even this effect seems to be counteracted, sometimes, by other circumstances.

The slow and moderate absorption of moisture by the powder S must be considered remarkable; since that powder contains 15 per cent. of coal, and has a very large proportion of fine grain.

Among the dense powders, the superiority of the powder B, with regard to the absorption of moisture, appears in all the tests to which I have subjected it. This may be owing, in part, to the more thorough charring of the coal, which in that powder is black, and not of the reddish hue of cylinder coal generally.

The fine state of preservation of the Waltham powder H, which, after 33 years, lost but 1 per cent. of weight by exposure to a hot sun, seems to leave nothing to desire on that score.

The very coarse grained powders, A. 0 and F. 0, absorb moisture slowly, as was to be expected from the comparatively small surface exposed. But they part with their moisture very differently from each other; for whilst the powder F. 0 returned very nearly to its original weight after drying, the powder A. 0, exposed to the same heat, still retained  $\frac{1}{15}$ th of its whole weight of moisture.

In order to form some idea of the relative destructibility of different kinds of powder, from the absorption of moisture, samples of many of them were tried by the musket pendulum, after having been dried. The results of this trial, and its comparison with the original trial of the same powders, before exposure to moisture, are presented in the following table of experiments with the musket pendulum.

#### SUMMARY OF THE EXPERIMENTS.

Table showing the relative force, by the musket pendulum, a various kinds of gunpowder in good order, and of the sam powders dried after exposure to air saturated with moisture

From this table it will be seen, that, in general, the least dense powders return nearest to their original strength; this is partly owing to the circumstance of their parting more readily with the moisture they had absorbed, and partly to not losing

#### HYGROMETRIC TEST OF GUNPOWDER.

their saltpetre by efflorescence. The powders A, G, N, R. 90', in which the efflorescence of saltpetre had been very great, became necessarily disintegrated, and they actually lost, as I have said, a notable proportion of their saltpetre. The powder A. 0, which lost nearly half its force, retained, it will be recollected, about 7 per cent. of moisture.

The remarkable result furnished by the powder E, in this trial, cannot fail to attract notice; on being dried after having absorbed about 23 per cent. of moisture, it has *increased* in strength, when fired in the musket. This seems to be easily explained when we consider that the density of this powder was, in its original state, so very great as to impede its combustion, although the materials were incorporated by an unusual degree of working. In drying, after exposure to moisture, the grain has become porous and remained permanently swollen; by this diminution of density, its combustibility has been increased in a greater degree than its strength has been impaired by the moisture, and hence results an actual increase in the force of the charge; the result would not be the same probably in a large charge, such as that of a 24-pounder gun.

## V. ANALYSIS OF THE EXPERIMENTS WITH THE CANNON PENDULUMS.

Although great care was taken, in the course of these experiments, to avoid, as far as practicable, those causes of irregularity which occur in ordinary practice, there still remain some minor variations, in the weight and windage of the balls, which could not have been prevented without a degree of labor and expense disproportionate to the object which would have been attained.

Before making a summary of the results of the experiments, for the purpose of comparison, it will be proper to reduce all 29

#### LOSS OF VELOCITY OF THE BALL

of the experiments of similar kind to a common standard, and the means of effecting these reductions are furnished by the special experiments made with balls of different diameters and weights. At the same time, in order to make an accurate comparison between the results given by the ballistic pendulum and those by the gun pendulum, the velocity with which the ball strikes the pendulum block will be reduced to that with which it issued from the muzzle of the gun, by adding to the former velocity, as indicated by the ballistic pendulum, the loss occasioned by the resistance of the air, whilst the ball is passing from the gun to the pendulum block.

We will begin with the last mentioned correction, and estimate :

# 1. The loss of velocity of the ball in passing from the gun to the pendulum block.

The resistance on a plane surface moving parallel to itself, through an incompressible fluid, is equal to the pressure of a column of fluid whose base is that of the moving surface, and its height that which is due to the velocity with which the surface is moved through the fluid; the resistance, on a given area, is therefore proportional to the square of the velocity. But the resistance on the surface of a sphere is half of that on the area of its great circle. Hence it is easily shown that, if

D represent the diameter of a ball;

v its velocity at any moment of its flight;

a the density of the air, that of water being unity;

G the measure of the force of gravity;

the retarding force f, acting on the ball, will be represented by  $\frac{3 a v^2}{8 G D s}$ , on the supposition that the ball moves through

a perfect and incompressible fluid .-- (See Hutton's Tracts, or any elementary work on Ballistics.)

#### BY THE RESISTANCE OF THE AIR.

But Hutton's experiments have shown that this supposition does not apply to the case of a ball moving through the air, and that in order to obtain the true resistance to such motion, it is necessary to multiply the theoretic resistance by a coefficient which varies with the velocity, according to a certain law determined from the experiments.

Calling this coefficient n, we have, for the retarding force,

$$f = \frac{3 n a v^2}{8 G D s}.$$

By the laws of retarded motion, v dv = -Gf dx; x being the space passed over when the velocity has been reduced to v; substituting the above value of f, we have:

$$v dv = -\frac{3 n a v^2}{8 D s} dx = -n e v^2 dx; \text{ putting } e = \frac{3 a}{8 D s}.$$
  
Hence,  $\frac{dv}{v} = -n e dx;$ 

and by integration,

Hyp. log. v = C - n e x;

but when x=0, v=V, the first, or initial velocity of the ball; therefore  $C = hyp. \log V$ ; this value, substituted in the preceding equation, gives:

Hyp. log. 
$$V$$
 — hyp. log.  $v$  = hyp. log.  $\frac{V}{v}$  =  $n c x$ ;

and if we put A = 2.718281828, &c., the number whose hyperbolic logarithm is 1, we have,  $\frac{V}{v} = A^{nex}$ ; consequently,  $V = v A^{nex}$ ;

a formula by which the initial velocity of the ball, or its velocity at the muzzle of the gun, may be determined by knowing the velocity with which it strikes the pendulum block.

In applying this formula to our experiments, I have taken x = 45 ft., which is a little less than the true distance (47.35 ft.) between the muzzle of the gun and the face of the pendulum block; because, as Hutton remarks, the resistance of

LOSS OF VELOCITY OF THE BALL

the air is counterbalanced at first by the pressure of the elastic fluid which accompanies the ball when it issues from the muzzle of the piece.

The value of the quantity  $e = \frac{3}{8} \frac{a}{Ds}$  may be conveniently

expressed in terms of the weight and diameter of the ball; for, *D* being the diameter in inches, and *w* the weight in pounds, we have:  $s = \frac{1728 \times 16 w}{1000}$ 

we have: 
$$s = \frac{1000 D^3 \times .5236}{1000 D^3 \times .5236};$$

and the density of the atmospheric air, at a mean temperature, near the level of the sea, being generally estimated at about  $\frac{1}{8 \cdot 50}$ th part of the density of water, we may put  $a = \frac{1}{8 \cdot 50}$ .

Therefore,

$$e = \frac{3 a}{8 s} \times \frac{12}{D} = \frac{3 \times 12 \times 523.6 D^2}{8 \times 850 \times 1728 \times 16 w} = 0.00010026 \frac{D^2}{w}.$$

The formula for the initial velocity of the ball,

$$V = v A^{nex}$$

is readily calculated, for any given values of v, n, e, and x; for, by taking the logarithms, it becomes:

Log.  $V = \log v + n e x \log A$ .

In this manner the following table of the loss of velocity of the ball, between the gun and the pendulum block, for the cases occurring most frequently in these experiments, has been computed.

The distance x is taken at 45 feet, as before mentioned; and to the coefficient n is assigned its appropriate value, varying with the velocity, according to the law determined by Hutton. The distance between the gun and the pendulum block is so small that the results of the calculations will not be sensibly affected by neglecting the change which occurs in the value of this variable coefficient, during the flight of the ball.

Log. A = 0.4342945; Log. log. A = -1.6377892

.

BY THE RESISTANCE OF THE AIR.

### 232 REDUCTION OF THE VELOCITES OF BALLS

### 2. To correct the velocities of balls for variations in weight.

The data for determining the relation between the velocities of balls of various weights, propelled by a given charge of powder, are furnished by those experiments, with both 32-pounder and 24-pounder guns, in which the weight alone of the ball varies, the windage and the charge of powder being the same.

The following table presents a summary of such experiments, the particulars of which may be found by reference to the Journal, or to the Synopsis which will presently be given. The velocities in this table are those obtained by means of the ballistic pendulum, reduced for the distance to the gun, by the rule just given. In order to extend the comparison to a greater variety of cases, I have introduced into this summary the results of some experiments in which corrections are made for small variations in the weight and windage of the balls, by the rules yet to be determined; but these corrections are too small to affect the general accuracy of the deductions.

#### FOR VARIATIONS IN WEIGHT.

Now, to determine from these experiments the relation sought for between the velocities and weights of the balls:

We will suppose that this relation may be expressed by an exponential function, and since the velocity diminishes as the weight increases, if we represent by m the exponent of that power of the velocity which is inversely proportional to the weight, and by V, v, the velocities of balls of which the weights are W, w, respectively, we shall have

$$\left(\frac{V}{v}\right)^m = \frac{w}{W};$$
  
log. w-Log. W

consequently,  $m = \frac{\text{Log. } w - \text{Log. } W}{\text{Log. } V - \text{Log. } v}$ .

By applying to this equation the values of V, v, W, w, furnished by experiments with balls of the same windage, &c., the values of the exponent m may be obtained.

In this way those values have been computed for the several series of experiments embraced in the foregoing table, by comparing the first term of each series with all the others in succession.

Notwithstanding some anomalies in the values of the exponent m, deduced from these experiments, the mean of the whole (2.11) differing but little from m = 2, tends to confirm the rule which has been generally received, that the velocities of balls of different weights, propelled by the same charge of powder, are nearly inversely proportional to the square roots of the weights.

The velocities computed according to this rule, which are contained in the last column of the above table, agree with the. experimental velocities, (except in one or two cases,) as nearly as will generally occur in experiments of this nature.

In the 4th No. of the Mémorial de l'Artillerie, there is a memoir of Col. Duchemin on the initial velocities of projectiles, containing formulæ deduced from experiments, which

## 234 REDUCTION OF THE VELOCITIES OF BALLS

have been considered worthy of insertion in the new edition (1844) of the Aide-Mémoire d'Artillerie. According to one of these formulæ, the initial velocities of balls of various weights, other circumstances being equal, are inversely proportional to the *fourth roots of the weights*. This relation between the velocities and weights is so far from representing correctly the results of the foregoing experiments, that we must suppose the author to have been led into error by deducing his formula from experiments which were not sufficiently numerous or varied to furnish the requisite data for an accurate solution of the question.

We shall have occasion to recur to this subject, after having prepared a synopsis of all the experiments.

In the mean time, we may safely conclude that, at least within the limits of variation in the weights of balls which occur in our experiments, the velocities may be reduced to those of a ball of standard weight, by correcting them according to the inverse proportion of the square roots of the weights. On this principle, therefore, the following table has been prepared for the purpose of facilitating such reductions, and of exhibiting, at the same time, the amount of correction in the cases that most frequently occur.

#### FOR VARIATIONS IN WEIGHT.

# 3. To correct the velocities for variations in the windage of the balls.

Numerous experiments have been made by me, with great care, on the effect of varying the windage of balls; but the question now under consideration is of so complicated a nature, that a complete mathematical solution of it (if indeed it be at all practicable) would require still a vast number of experiments to furnish the requisite data. This will appear evident, when we consider that the loss of velocity by a given increase of 30

#### 236 REDUCTION OF THE VELOCITIES OF BALLS

windage probably depends on :

- 1. The degree of windage;
- 2. The calibre of the gun;
- 3. The length of bore;
- 4. The kind of gunpowder;
- 5. The charge of powder;
- 6. The weight or density of the ball.

The influence of some of these causes, however, is no doubt inconsiderable, and we may derive, from our experiments, an estimate of the loss of velocity which is occasioned by such increase of windage as occurs in ordinary practice with 32-pounder and 24-pounder guns. For this purpose, the experiments have been made with balls of such diameters as to represent the least and the greatest windages which could occur with new guns and balls, of diameters within the prescribed limits; and also the greatest windage of the ball in a 24-pounder gun, the bore of which should be so much enlarged as to cause its rejection from service. Some experiments have likewise been made with balls having but little more windage than would just allow them to enter the bore of the gun; but these experiments were too hazardous to be often repeated, or to be tried with large charges of powder.

In the following synopsis of these experiments on windage, the velocities of the balls have been reduced to those of a ball of standard weight, by the rule before established. The balls of each calibre might have been made to correspond actually in weight, as was done in some of the experiments with the 24-pounder gun; but it was apprehended at first, that the accuracy of the experiments might be impaired by the irregularity in the place of the centre of gravity of the ball, (with reference to its centre of figure,) which would have been occasioned by the use of shells partially filled up.

# FOR VARIATIONS OF WINDAGE.

,

Summary of experiments on windage, with the 32-pounder gun.

We will now bring these results into one view, as in the following table:

By taking the difference between the first windage and each of the others, in each set of experiments, and the corresponding differences of velocity, and then dividing each of these differences by the first of its series, we obtain the ratios between the several differences of windage, and between the corresponding differences of velocity. These ratios approach

#### FOR VERIFICATIONS OF WINDAGE.

so nearly to equality as to authorize the conclusion that the differences in the velocities of balls of different diameters are proportional to the differences of windage; or, in other words, that the loss of velocity by windage is proportional to the windage.

This relation between the windage and the loss of velocity, corresponds with the rule laid down by Hutton, and it appears to be consistent with reason. For the force exerted on the ball by a given charge of powder, is proportional to the quantity of the inflamed fluid which acts on the ball; but the force is also proportional to the square of the velocity. Therefore the difference of the squares of the velocities imparted to balls of different diameters, is proportional to the difference in the quantities of inflamed fluid acting on the balls, or to the loss of fluid by the difference of windage; and this loss is as the area of the opening through which the fluid escapes, or as the difference between the areas of the squares of their diameters. Therefore, if V, v, v' represent the velocities of balls, the diameters of which are D, d, d', we shall have:

 $V^2 - v^2 : V^2 - v'^2 - :: D^2 - d^2 : D^2 - d'^2;$  consequently,

(V+v')(D+d)(V-v')(D-d) = (V+v)(D+d')(V-v)(D-d').

But since the velocity increases with the diameter of the ball, and since the variations in the values of v and d are generally small, we may consider the terms (V+v') (D+d) and (V+v)(D+d') as being nearly equal; therefore, the remaining terms are also equal; that is to say,

(V - v') (D - d) = (V - v) (D - d');

from which it follows that the loss of velocity is proportional to the difference of windage. Or, if V represent the velocity of a ball whose diameter D is equal to that of the bore, then the

#### 242 REDUCTION OF THE VELOCITIES OF BALLS

if,

total loss of velocity by windage will be proportional to the windage, other circumstances being equal.

In order to apply this principle to the reduction of the velocities obtained in our experiments, with balls having slightly different diameters, divide the last equation by V(D-d), and  $\frac{V-v'}{V} = (D-d') \frac{V-v}{V(D-d)};$ it becomes

if, therefore, we determine by experiment the value of the factor 
$$\frac{V-v}{V(D-d)}$$
, for any difference of windage or difference of diameter,  $D-d$ , and denote this value by  $m$ , we shall have,

of o ve, for any other difference of diameter, (all other circumstances being equal,)

 $V - v' = V \times m \ (D - d').$ 

The experiments above recited show that the value of the coefficient *m* varies with the kind of powder used; that is to say, that the loss of velocity by the same difference of windage is not the same for different kinds of powder. There can be no doubt, too, that the value of m varies with the calibre of the gun and with the charge of powder; but the calibres and charges used in these experiments on windage do not differ from each other sufficiently to develope the law of this variation, and as the same charges were employed in most of the experiments, the results of which we are now preparing to reduce, I have thought that it would be safe to use, in these reductions, a mean value of m for each kind of powder, applying to each kind the coefficient obtained for the powder A, F, or G, most nearly resembling it.

Having had occasion to mention Col. Duchemin's practical formulæ for determining the initial velocities of balls, I may remark that, in estimating the loss of velocity by windage, he appears to have been again led to an erroneous conclusion by the want of sufficient data; for he makes the loss of velocity

#### FOR VARIATIONS OF WINDAGE.

proportional to the square root of the windage, other circumstances being equal; which ratio is far from representing the results of my experiments. According to Col. Duchemin's formula, also, the ratio of the loss of velocity to the total velocity is independent of the calibre of the piece. Now, although, as before remarked, the difference between the bores of the 32-pounder and the 24-pounder is not sufficiently great to produce a decided change in the proportional loss of velocity by a given windage in those guns, yet, if we compare these experiments with others, made with guns of much smaller calibre, we shall find that the value of the coefficient m, which expresses the proportional loss of velocity, varies decidedly with the calibre of the piece. For this purpose I may refer to the very experiments quoted by Col. Duchemin in support of the truth of his formula, being indeed the only experiments of the kind which have been published; I mean those made by Hutton and by Gregory, at Woolwich, with the ballistic pendulum.

The following is a summary of the results of those experiments, the particulars of which may be found in the authors' reports. In order to facilitate the comparison of the results with each other, the initial velocities are reduced to a common measure, in the proportion of the square root of the weight of the ball inversely, and the square root of the charge of powder directly. The kind of powder used in these experiments may be considered as similar to the powder A in my experiments.

Experiments on windage.

If there should even be an error in the rule for the correction of velocity which I have deduced from my experiments, it fortunately happens that the variations of windage of the balls used in the experiments to which this rule will be applied, are too small to produce, in the results, any error of sufficient magnitude to impair the correctness of the deductions which may be made from those experiments. According to this rule, therefore, the following table has been computed for reducing the initial velocities to a common standard of windage.

# FOR VARIATIONS OF WINDAGE.

# Table showing the reduction of velocity of 32-pounder and 24-pounder balls for a given difference of windage.

Digitized by Google

#### REDUCTION OF THE EXPERIMENTS

#### Reduction of the experimental velocities of cannon balls to a uniform standard of comparison.

Having thus obtained the means of reducing to a common standard the results of the experiments with the cannon pendulums, I shall now present a synopsis of them, showing the principal elements of each case, the velocity of the ball obtained from experiment by the gun pendulum as well as by the ballistic pendulum, and the corresponding velocity reduced to a uniform standard of weight and windage, and corrected, when necessary, for the distance between the gun and the pendulum.

In adopting a standard weight for the balls of each calibre, I have regarded the grommet wad as forming a part of the weight of the ball, since the wad is propelled from the gun with a velocity not less than that of the ball; the standard weight adopted is therefore the mean weight of the ball and grommet together.

The date of each experiment is given, for the purpose of easy reference to the Journal, in which all the particulars of the case may be found.

#### Reduction of the experiments with the 32-pounder gun.

Note.—The velocity with which the ball strikes the pendulum block is reduced to that with which it issues from the muzzle of the gun.

All the velocities are reduced to those of a ball of the windage of 0.173 in. and of the standard weight noted in the column of remarks.

# WITH THE 32-POUNDER GUN.

Experiments with the 32-pounder gun-(Continued.)

# with the 24-pounder gun.

# Reduction of the experiments with the 24-pounder gun.

N. B. The velocity of the ball at the pendulum block is reduced to that at the muzzle of the gun. All the velocities are reduced to those of a ball of the windage of 0.135 in., and of the standard weight noted in the column of remarks.

wITH THE 24-POUNDER GUN.

•

259

teduced to ball of 0.007 in. windage, and 24.25 lbs. weight. teduced to weight 24.25 lbs. 33

#### SUMMARY OF THE EXPERIMENTS

#### Summary of the experiments with the cannon pendulums.

For more convenient reference, in analysing and comparing the results of these experiments, I have prepared the following summary, showing the mean results of all the experiments of a like kind, reduced to a common standard.

| ds.            | POW             | DER.              | BA         | LL.        |                           | TIAL<br>City.        |                             |

#### WITH THE CANNON PENDULUMS.

267

# Comparison of the initial velocities deduced from the two pendulums.

In examining the preceding summary of the experiments, we are struck with the coincidence in the results obtained by means of the two pendulums. The only exceptions, worthy of notice, occur in the experiments with high charges in the 32-pounder gun, and with very light balls in the 24-pounder; and in these instances, the discrepancies may be explained by reference to the remarks made in the discussion of the formula for the velocity of the ball by the recoil of the gun pendulum. For, all of our reasoning on the useful effect of the charge of powder rests on the supposition that the powder is entirely inflamed, or its force fully developed, before the ball leaves the gun, and this supposition will be further from the truth in proportion as the bore of the gun is shorter in comparison with its diameter, or as the charge is greater in proportion to the weight of the ball. In the case of a wooden ball fired from the 24pounder gun, with a charge nearly equal to the weight of the ball, it is probable that the velocity of the ball at the ballistic pendulum is not accurately represented on account of the great disproportion between the weight of the pendulum and that of the ball; but even in this case, it would seem, by a comparison of the velocities and weights, that the error cannot be very great.

The general coincidence of the results obtained by the gun pendulum with those by the ballistic pendulum, in such a number and variety of cases, cannot be considered accidental, and it affords strong presumption of the correctness of the formula by which the former results are computed.

This coincidence of results is of great interest in a practical point of view, not only because it furnishes the means of verifying the accuracy of the experiments, but because, by the use

#### RELATIVE FORCE OF

of the gun pendulum alone, we may extend them much beyond the limits to which we should be restricted if it were necessary always to employ the ballistic pendulum. It is still more important, in reference to the use of this apparatus for the proof of gunpowder; as it may enable us to dispense with the service of the ballistic pendulum for that purpose, and thus render the operation much less tedious and expensive.

In discussing the relative force of various kinds of powder, reference will be generally made to the velocities obtained by the ballistic pendulum only.

#### RELATIVE FORCE OF VARIOUS KINDS OF CANNON POWDER.

In the following tables, the results of the experiments with different kinds of powder, under the same circumstances, are brought together, for the purpose of facilitating a comparison of their force, when fired in cannon of large calibre.

As the effect of the charge of powder is measured by the quantity of motion it imparts to the ball, the force of the powder, with balls of the same kind, is proportional to the velocity of the ball. To make the comparison more easy and obvious, the velocities communicated to the balls by the several kinds of powder are compared with those given by the powder G. 6, which has the greatest force in all cases, and the ratios are set down in the column of *relative force*. In cases where no experiments were made with the powder G. 6, I have interpolated the velocity with that powder, in order to preserve a uniform standard of comparison.

# Relative force of various kinds of gunpowder, as indicated by the gun pendulums, with blank cartridges.

#### REMARKS.

1. These results agree in classing the different kinds of powder in the same order of relative force, by the 32-pounder and the 24-pounder guns, with all the charges tried, both with shot and shells.

Any exception to this remark, that may be observed, is too slight to require notice.

The ratio of force, compared with that of the strongest powder, is not precisely the same in all cases, as that ratio approaches somewhat nearer to equality with the smaller charges; but even with these, the powders preserve the same order of force.

#### RELATIVE FORCE OF

272

In comparing, therefore, the different kinds of powder, we may refer to the experiments with the 24-pounder gun, with the charge of 6 lbs.; as it is with that charge that the most numerous trials have been made.

Although the results with blank cartridges class the several kinds of powder in nearly the same order of relative force as those with balls, yet the differences in the ratio of force, by the two methods, are so great as entirely to preclude the hope of obtaining an accurate test of the strength of gunpowder by firing blank charges from a gun of any calibre.

# 2. Influence of the size of grain on the force of cannon powder.

Within the limits of the difference in the size of grain which occurs in ordinary cannon powder, the granulation appears to exercise but little influence on the force of the powder, unless the grain be exceedingly dense and hard. Thus it will be seen that, although in the cannon powders A, B, C, and D, the largest grain has a slight advantage in force over the smallest, yet the difference is generally unimportant, and the very coarse grain A. 0, which is ten times larger than the largest grain of the ordinary cannon powder, has nearly the same force as the latter. But the force of the powder E, the density and hardness of which are carried to excess, is very much affected by the size of grain, even when the difference of size is not very great, as in the cases of E.1 and E.3. This effect is still more remarkable, when we pass to the very fine grain of the dense powders, E. 5 and G. 6, the force of which is vastly greater than that of the large grain E.1 and G.1. On the other hand, the mealed power A. m (which is made by reducing mill cake to dust) is so minutely divided as to reduce its force to about three-fourths of that of similar powder in

#### VARIOUS KINDS OF CANNON POWDER.

grain; the powder lying in such a compact mass that the flame penetrates it with difficulty.

On the whole, the usual mixture of grain, as in the powder A, appears to be favorable to the development of the force of powder in guns of large calibre.

The difference in the force of the several sizes of grain sifted from the same cannon powder being inconsiderable, I have, in the preceding tables, taken a mean of the whole, to represent the average force of each distinct kind of powder.

# 3. Influence of different proportions of the ingredients of powder.

A comparison of the force of the pounding mill powders K. 1. g. and M. 1, and of the rolling mill powders N and X, indicates that there is no marked superiority in either of the proportions 76, 14, 10 or 75, 12.5, 12.5; neither do the proportions of the sporting powder G. 1 appear to possess any advantage over the others, when worked into large grain. The great strength of the powder S, which is incorporated in a similar manner to N and X, but contains only 70 per cent. of nitre, would seem to show that the quantity of nitre might be reduced much below the usual proportion, without sensibly altering the mere strength of the powder when new; such powder would probably not be well preserved for any considerable time, but the fact of its strength, if confirmed by further trials, may furnish a useful hint, in case of a necessity for economizing saltpetre, in making powder for immediate It is probable that the force of this powder S is partly use. due to the great inequality in the size of grain, and to the large proportion which it contains of fine grain.

#### 4. Influence of different modes of manufacture.

The highest degree of strength in the cannon is exhibited by powder made under the heavy rollers by the process now

### RELATIVE FORCE OF

generally adopted in England and at the principal powder works in this country. But the superiority of this method of incorporation, although uniform and decided, is not so great as to give it an absolute preference over all other methods, so far as regards the strength alone of the powder; and the choice between them may be determined by their relative economy, and by an examination of the other qualities which they im-Thus the mean velocity of the 24-pounpart to the powder. der ball by 6 lbs. of all the rolling mill powders (a, A, G. 1,H, M.1, N, R. 90', S and X) is 1643 feet, not very different from the mean of the results obtained by other kinds of powder of similar density. I omit the powder C in this enumeration, because the mill charge and the time of running do not conform to the usual practice in the best mills, although the effect of that mode of working, on the strength of the powder, would seem to be nearly the same as that of the common practice.

The efficiency of the method of incorporation by means of heavy rollers is shown by a comparison of the powders R, which differ from each other only in the time of running under the rollers, the coal and sulphur having been previously pulverized. It appears that powder worked not more than 30 minutes in this way has nearly as much strength as the powder F, made of similar materials, by 14 hours' work in the pounding mill; but it must be remarked, that the cylinder coal used in making these powders is not considered suitable for working in the pounding mill, being too hard to admit of sufficient pulverization by the action of the pestles. In the manufacture of powder for the French military service, in which the pounding mill alone is used, the coal is therefore charred in open pits, (à l'air libre,) by which means it is more thoroughly burnt and much more friable than the cylinder coal. The difference in the use of these two kinds of coal,

### VARIOUS KINDS OF CANNON POWDER.

275

for pounding mill powder, is exhibited by comparing the powders F and K 1. r., which differ only in this respect. The strength of the powder K shows that the pounding mill is capable of manufacturing powder of great force; but this sample is decidedly superior to the ordinary French cannon powder, which, under the same circumstances, would give to the 24pounder ball a velocity of about 1540 feet, instead of 1640. This superiority is due partly to the longer time of working on the powder K; (14 hours instead of 11, as in the French mills;) partly to its being free from dust; and partly to the better quality of the coal, owing to its having been prepared on a small scale, and therefore more carefully than in large pits. It would appear that 14 hours is nearly the limit of useful work under the pestles, as scarcely any additional force is gained by 24 hours' work, which was employed in making the powder L.

The results obtained with the powder G. 1 show that, for cannon powder, no advantage, in point of strength, is gained by the thorough working and great density which are favorable to the production of the greatest force in small grain powder, such as G. 6.

The force retained by the Waltham powder H, after having been kept, without especial care, for thirty-three years, furnishes strong evidence in favor of the English mode of manufacture.

I am at a loss to explain the difference between the strength of the powders a, N and X, and that of the powder A, otherwise than by supposing that, notwithstanding the previous pulverization of the materials, one hour's work, even under very heavy rollers, is not sufficient to ensure uniformity in the quality of the powder. But there may have been some peculiarity in the working of the powder A, such as the mixture of the dust of former working, which would account for its superior strength; it must be remarked, however, that the same 35

Digitized by Google

### RELATIVE FORCE OF

superiority was found in all the trials of this powder, which has been taken from ten different barrels.

A comparison of the strength of the powder T with that of S, or of ordinary cannon powder, shows that there can be no real economy in the use of inferior and cheap powder for blasting rocks.

From the experiments with the powders C and D, in which the saltpetre is far from being refined to the proper standard, it appears that a notable proportion of foreign salts may exist in the nitre, without sensibly impairing the strength of the powder when it is new, or when it has been well preserved for a moderate time. Hence the great importance of using proper tests, besides the mere proof of the force of powder, for determining this point, so essential to the due preservation of the strength of powder in service.

### 4. Influence of the density of powder on its strength.

By whatever means a thorough incorporation of the ingredients of gunpowder may be effected, it is evident that a very considerable degree of density is requisite for the full development of its force in the cannon. But there is a limit beyond which an increase of density is no longer favorable to the strength—this limit is passed in the powders E and G. 1, in both of which, the density and hardness of the grain are too great for cannon powder. This will be apparent by comparing the force with the size of grain in each of these powders; for whilst in most of the other kinds, the force decreases with the size of grain, it here increases in a great ratio as the grain becomes smaller.

Thus also it will be seen, by comparing the pounding mill powders F and K, that the density of the former is much below the proper standard for strength. Of all the samples tried, the lowest density which appears consistent with great force in

### VARIOUS KINDS OF CANNON POWDER.

the cannon, is that of the rolling mill powders H and R. 90', the gravimetric density of each of which is nearly 870. On the other hand, it does not appear necessary, on the score of strength, as it is certainly not advisable in other respects, that the gravimetric density of the coarse grain of cannon powder should exceed 920.

# 5. Influence of glazing, on the strength of powder.

As it is considered necessary that all the powder for the military service should be glazed, in order to prevent the formation of too much dust in its transportation, but few experiments were made on this subject. The only direct comparison between glazed and rough powder was with the powders K.1.r.and K.1.g., the former of which is rough, and the latter glazed; both being nearly free from dust, there is no appreciable influence exercised by the glazing on the strength.

No experiment was deemed necessary to prove that the greater quantity of dust formed from unglazed powder in transportation impedes the penetration of the flame through the charge, and therefore materially diminishes its force.

6. The great and uniform superiority of the fine sporting powder, G. 6, even in large charges in the cannon, evinces the combined effect of the most careful preparation of the materials, their thorough incorporation, perfect drying, and high glazing; all of which are favorable, not only to the production of the greatest inherent force of the composition, but to the quick combustion of the grains, and to the rapid transmission of the flame through the whole mass of powder.

# 278 RELATION OF THE VELOCITY OF THE BALL

### OF THE RELATIVE INITIAL VELOCITIES OF BALLS OF DIFFER-ENT DENSITIES, PROPELLED BY VARIOUS CHARGES.

In the previous discussion of the relation between the weights and velocities of balls of equal diameters, for the purpose of reducing the experimental velocities to a common standard of weight, it appeared that, for small variations of weight, the common rule of the velocity being in the inverse ratio of the square root of the weight may be adopted without sensible error; although it does not represent, with accuracy, the results of the experiments when the variation of weight is very great.

This might indeed have been anticipated; for the rule in question would indicate that the force generated by the inflamation of a given quantity of powder is always the same; whereas, it is well known that the tension of the gaseous fluid increases with the resistance opposed to its expansion. Thus, Robins and others, reasoning from the effects of the charge in a gun, have estimated the force of fired gunpowder at from 1,000 to 10,000 atmospheres; whilst Count Rumford, by burning the charge in a confined space, under heavy pressure, makes the force equal to 40,000 atmospheres. It follows, therefore, that no function of the weight of the ball alone can express its relation to the velocity communicated to it by a given charge of powder.

Again, it has been usual to consider that the velocities communicated to the same ball, by different charges of powder, are proportional to the square roots of the charges. But this rule rests on a similar supposition to the preceding—that the force produced by the combustion of the charge is proportional to the quantity of powder; whereas, it is obvious, that the portion of the charge which acts with the maximum effect on the ball, (that is to say, which exerts its force before the ball has been much displaced.) will vary with the resistance, or with

### TO ITS WEIGHT AND TO THE CHARGE OF POWDER. 279

the density of the ball; this density must therefore enter into the expression of the relation between the velocity of the ball and the charge of powder.

It appears, therefore, that although the weight of the ball or the charge of powder should remain the same, (the other being varied,) the corresponding variations of velocity must be expressed in terms of both those quantities.

We are indebted to M. Piobert for the suggestion of an empirical formula which appears to express, with great accuracy, this compound relation of the velocity, weight, and charge. This formula I find in the report of experiments at Metz, contained in the 4th No. of the Mémorial de l'Artillerie.

Putting b for the weight of the ball, and c for that of the charge of powder, Piobert's formula makes the velocity of the ball proportional to  $\sqrt{\text{Log.}(1+\frac{c}{b})}$ ; the charge being such, in proportion to the weight of the ball and to the length of the gun, that the powder may be supposed to act on the ball whilst the gaseous fluid retains a high degree of tension. This he considers to be the case with any charge not exceeding half the weight of the ball, in a gun of not less than 17 calibres length of bore.

The following comparative statement of the experimental and computed velocities of balls of different weights, propelled by the same charge of powder, shows how nearly this formula agrees with the experiments :

| gun.            | Kind of powder. |              | BAI    | L's            |              | BALL'S       |                | ł  |

# 280 RELATION OF THE VELOCITY OF THE BALL

The velocities v, in the last column of this table, are commuted from the first velocities V, by the formula

$$v = V \frac{\sqrt{\operatorname{Log.}(1 + \frac{c}{b})}}{\sqrt{\operatorname{Log.}(1 + \frac{c}{B})}};$$

and the correspondence of the results of this computation with

### TO ITS WEIGHT AND TO THE CHARGE OF POWDER. 281

hose of the experiments is, with few exceptions, remarkably close.

Denoting by M the constant ratio

$$\frac{v}{\sqrt{\text{Log.}(1+\frac{c}{b})}} = \frac{V}{\sqrt{\text{Log.}(1+\frac{c}{B})}}$$

we shall have

$$v = M \sqrt{\text{Log.}\left(1 + \frac{c}{b}\right)}$$

which is the formula given by Piobert for expressing, in general, the velocity of the ball in terms of its weight and that of the charge of powder.

In the preceding table it is shown that M may be regarded as constant in cases when the weight of the ball alone varies, all other circumstances being the same. But the author proposes to apply the formula in a much more general manner, and to consider M as constant for all values of c and b in the same gun, with the same powder and with balls of the usual windage, (if not with all balls of the same windage,) provided the length of bore and the proportion between the powder and ball be within the limits before mentioned.

To ascertain how far this supposition is consistent with facts, I have computed the values of M, from my experiments, for various charges of several kinds of powder, as expressed in the following table:

| 32                 | -POUNDER            | GUN.                          | 24-р               | OUND    | ER GUN.                       |                      |

# 282 RELATION OF THE VELOCITY OF THE BALL

### TO ITS WEIGHT AND TO THE CHARGE OF POWDER. 283

By this table we see that, although the value of M decreases, in most cases, as the charge increases, we may assign to that coefficient a mean value which will not lead to any great error in estimating, by the above formula, the velocity of the ball for charges not exceeding *one-third* of its weight. Beyond this limit, with the dense kinds of powder at least, the velocity increases in so small a ratio with the increase of charge, that the same coefficient no longer represents it correctly.

The variations in the value of M, for the several kinds of powder, a, A, B, C, and D, which compose the principal part of our present stock of cannon powder, are not so great as to prevent our using its mean value to express the force of these powders. We may therefore conclude, that by assigning to Mthe value of 5,200 for the 32-pounder gun, and 5,400 for the 24-pounder, the formula will give, with sufficient accuracy, the velocity of balls of the true windage, (0.16 in. and 0.14 in. respectively.) from those guns.

It will be remarked, that there is also a close agreement in the values of the coefficient M, obtained from the velocities of balls of other corresponding diameters, propelled by different charges of the same powder; which shows that the formula applies to all the usual cases of practice, by giving the proper value to M.

The experiment of 25th August, 1844, in which a 24pounder ball, with very small windage, was fired, with the vent of the gun closed, gives for the coefficient M, the value of 6,334, which may be regarded as very nearly its maximum value for the 24-pounder gun, and as furnishing the means of computing the greatest velocity which can be communicated to a ball fired from that gun, with any ordinary charge of the powder A. On this principle, the maximum velocities in the following table have been computed.

OF THE LOSS OF FORCE BY WINDAGE.

|                 | POW               | DER.                     | ball.                     | INT                                     | TIAL VELO                             | CITY OF BA            | LL.                   |
|-----------------|-------------------|--------------------------|---------------------------|-----------------------------------------|---------------------------------------|-----------------------|-----------------------|
| Gun.            | Kind.             | Weight.                  | Weight of 1               | Without<br>windage.                     | Windage<br>0.135 in.                  | Windage<br>0.245 in.  | Windage<br>0.355 in.  |
| 24-pounder<br>" | <b>A.</b><br><br> | Lbs.<br>3<br>4<br>6<br>8 | Lbs.<br>24.25<br>''<br>'' | . Feet.<br>1426<br>1631<br>1963<br>2229 | Feet.<br>1255<br>1450<br>1702<br>1882 | Feet.<br>1332<br>1596 | Feet.<br>1197<br>1465 |

By comparing these results, an estimate may be formed of the loss of force by the windage of the ball. Thus it will be seen that 4 lbs. of powder give to a ball without windage, nearly as great a velocity as is given by 6 lbs. to a ball having the windage of 0.14 in., which is considered the true windage of a 24-pounder ball; or, in other words, this windage causes a loss of nearly *one-third* of the force of the charge.

In my former remarks on the subject of windage, it has been stated, that the loss of velocity by the same windage is different for different kinds of powder; the light pounding mill powder F losing a smaller proportion of its force than the dense rolling mill powders A and G. This is undoubtedly favorable to the former kind of powder, but the advantage in this case is counterbalanced by the fact, that the velocity of the ball by the powder F is still inferior to that by the powder A, with the windage increased 0.11 in., as will be seen by reference to the experiments on windage with the 24-pounder gun. The result, however, affords an argument in favor of reducing the density of the rolling mill powders, and thus increasing their quickness of burning in a mass.

The following table shows the results of the experiments relative to the loss of force by the vent of the gun:

These experiments, although not very extensive, are deemed sufficient to show that the loss of force, by the escape of gas from the vent, is altogether inconsiderable, when compared with the whole force of the charge, or with the other unavoidable variations which affect the velocity of the ball.

This result might have been anticipated, when we reflect that the orifice for the escape of gas through a vent of 0.25 in. diameter, is equal only to the difference between the areas of the great circles of balls whose diameters are 5.68 in. and 5.6745 in.; and the orifice of a vent of 0.175 in. diameter is equivalent to a diminution of windage of only 0.0027 in. in a ball of 5.68 in. diameter.

### 286 OF THE USE OF PERCUSSION PRIMERS FOR CANNON.

In the preceding comparison, I have not included the experiments made with balls of 0.007 in. windage, because there was but one ball fired with the vent closed; and, in that case, the increase of velocity over that of the others is obviously too great to have been caused by the mere closing of the vent, and must be attributed to some accidental variation; probably to a slight difference of windage, which may have easily escaped observation where the whole windage was so small.

OF THE EFFECT OF USING PERCUSSION PRIMERS.

The following experiments with the 24-pounder gun show that no influence on the force of the charge in a cannon can be attributed to the use of percussion primers for igniting the powder:

| unds.          | POWE  | ER.     |            | f ball.          |  |

### OF THE EFFECT OF WADS.

In the experiments with the cannon pendulum the ball was habitually kept in place by means of a very light *grommet*, or ring of rope yarn; a few experiments were made in firing balls without grommets, and also in putting hay and junk wads over the balls, as will be seen by reference to the summary of the experiments.

### OF THE USE OF WADS FOR CANNON.

By reducing the velocity impressed on the ball and wad, conjointly, to that of a ball of the standard weight, it is found that very little effect on the force of the charge is produced by the use of the hay or junk wads. The velocity of the ball is somewhat less than when fired with a grommet, indicating perhaps that the motion of the ball in the bore is more impeded by the friction of the wad than it is accelerated by the slight additional force which is developed in the charge by reason of the increased resistance. There can be little doubt that the wad diminishes the velocity of the ball very nearly in the proportion of the increased weight; but the great deviation caused by the wads, in the direction of the balls, obliged me to desist from continuing these experiments, for fear of injury to the ballistic pendulum.

The experiments which were afterwards tried, on the effect of wads in causing the deviation of the ball, (for the particulars of which I refer to the Journal, under date of May 28th and 29th, 1844,) show conclusively that the use of hav or junk wads is decidedly injurious to the accuracy of fire; and that when a wad is required to hold the ball in its place, it should be made as light as possible, in the form of a grom-This conclusion is confirmed by similar experiments met. made with 32-pounder and 24-pounder guns at Washington Arsenal in 1844, under the direction of Major Symington. In these experiments it was found that the accuracy of fire was not affected by a sabot, or a hay wad, placed between the powder and ball; a result of great practical value, since, by this use of the wad or sabot, we are enabled to increase the durability of guns, and especially of brass guns, by changing the position of the ball, without impairing the accuracy of fire.

These facts, relative to the effect of wads, have been long known, I believe, in the naval services of France and England, and have led to the general substitution, in those ser-

### 288 OF THE EFFECT OF VARYING THE DIAMETER

vices, of the grommet, for the inconvenient and costly junk wad.

The following experiments were made with cartridges of different diameters and lengths:

From this table it appears, that whilst the usual diameter of the cartridge, for the 24-pounder gun, as now established, (5.35 in.) is favorable to the development of the force of the charge, no great diminution of effect arises from reducing the diameter to 5 in.; on the other hand, the force of the charge is vastly reduced by increasing the diameter of the charge to the full size of the bore. The latter effect is readily understood when we consider, that, in this case, the flame is communicated to the front part of the charge only by penetrating through the mass of powder; the ball must therefore be a good deal removed from its first position before the whole of

### OF CANNON CARTRIDGES.

the charge becomes inflamed, and consequently the gaseous fluid, expanding in a larger space, has its tension proportionally reduced; this effect, too, will be greater in proportion as the density of the powder increases, and presents a greater obstacle to the rapid combustion of the charge.

The experiments of the Board of officers at Metz, whose Report I have mentioned in the beginning of my Journal, show that, with charges exceeding one-fourth the weight of the ball, the cartridge of diminished diameter has even the advantage in point of force, and this circumstance assumes great practical importance when taken in connection with another fact developed by numerous experiments in France, viz: that by reducing the diameter of the cartridge, the strain on the gun may be greatly diminished.

In order to prevent the very rapid destruction of brass siege guns, which is caused by the use of large charges, Capt. Piobert proposed, in a memoir written in 1833, to increase the space in rear of the ball, by diminishing the diameter of the cartridge, or by interposing an elastic wad between the powder and ball. Numerous experiments on the relative injury to brass guns, by using the common and the elongated cartridge, have fully realized M. Piobert's anticipations, by showing that whilst the increase of diameter in the gun is much diminished by the use of the long cartridge, the force of the charge in its action on the ball is not lessened, but in many cases increased; and to effect this object it has not been found necessary to make the cartridge of an inconvenient length.

The most full and careful experiments which have been made on this subject are those of the Board of officers just mentioned. For the particulars of these experiments I must refer to their Report, a copy of which has been so obligingly furnished to the Ordnance Department by the French Minister of War. It is sufficient to state here the general result of these experi-

### 290 OF THE EFFECT OF VARYING THE DIAMETER

ments: that by reducing the diameter of the cartridge for the 24-pounder gun (the bore of which is 6 in. diameter) from 5. in. to 5.15 in., which increases the length of the cartridge abour 2 in., the enlargement of the area of the section of the bore (produced by 4 rounds with a charge of half the weight of the ball,) is reduced *four-fifths*, whilst the initial velocity of the ball, as before stated, is somewhat increased; and this result is confirmed by numerous experiments with other large charges.

This effect of increasing the length and diminishing them\_t diameter of the cartridge, seems to admit of an explanation similar to that which I have suggested, with regard to the operation of the charge when the cartridge is of the whole size o. the bore. For, in the present case, the flame produced by them .e combustion of the first, or hinder, part of the charge, expander 18 rapidly in the empty space above the cartridge; its tension , and the consequent strain on the gun, before the ball is moved are, therefore, much less than in the ordinary case of a large and shorter cartridge. At the same time, in consequence of this rapid expansion of the flame, it is communicated more quickly to the front part of the cartridge than when it has to pass through the mass of powder; and so much the more quickly in proportion as the transmission of the flame through the powder is more difficult, or as the powder is more dense. and the charge greater. Consequently, the complete inflammation and combustion of the whole charge, producing the final velocity of the ball, take place under these circumstances in a smaller space than before, although that space is sufficiently great to reduce very much the intensity of the action of the powder on the sides of the bore.

Be the explanation as it may, the facts are considered, in the French service, to be so well established that, in the new edition of the Aide-Mémorie d'Artillerie, in 1844, the princi-

#### OF CANNON CARTRIDGES.

ple of reducing the diameter of the cartridge is adopted for all siege and garrison guns.

Although the range of my experiments did not allow me to verify these results, I have permitted myself to make the foregoing remarks on the French experiments, in order to call the attention of the Ordnance Department to a matter which may be of the greatest importance to us, in reference to giving increased durability to our iron guns, and diminishing the risk of accidents which have been lately of frequent occurrence from the bursting of these guns.

# COMPARISON OF THE RESULTS OF EXPERIMENTS ON RANGES WITH THOSE OBTAINED BY COMPUTATION.

The position of the pendulum gun offering a facility for determining points in the trajectory of a ball fired horizontally, I was induced to make some experiments on that subject, as explained in the Journal. The initial velocities of the balls having been determined by the recoil of the gun pendulum, and afterwards by firing with similar charges at the ballistic pendulum, an opportunity was thus afforded of making the comparison now under consideration.

In computing the theoretic ordinates of the trajectory at different distances from the gun, I have used the following equation of the trajectory at low angles, which applies to ranges not exceeding 2,000 feet:

$$y = x \tan \theta - \frac{g x^2}{6 c v^2} (3 c + 2 x)$$

in which

- y, is the ordinate, or the distance of any point in the trajectory from the horizontal plane passing through the muzzle of the piece.
- x, the abscissa, or the distance of the ordinate y from the muzzle of the piece.
  - 37

### 292 COMPARISON OF THE EXPERIMENTAL WITH THE

- , the angle of elevation, or, strictly speaking, the angle of departure of the ball; that is to say, the angle which the first direction of the ball makes with the horizontal plane.
- v, the initial velocity of the ball.
- g, the force of gravity.
- $c = \frac{n}{e}$ ; n and e being the same terms that were used in

estimating the loss of velocity by the resistance of the air: Page 229.

The axis of the gun being always horizontal in my experiments, I have, in computing the values of y by the above formula, considered tang.  $\phi = 0$ . This supposition is not strictly accurate, in consequence of the irregularities produced in the direction of the ball by its striking against the sides of the bore, as indicated in the Journal of experiments by the variations in the position of the point struck, at the first target, near the muzzle of the piece. But as in ordinary practice we have no means of ascertaining this anomaly, our calculations must be made on the supposition that the ball leaves the piece in the direction of the axis of the bore, and they are accordingly thus made in the present case; the errors in the results are probably unimportant, as those in opposite directions will generally balance each other.

In computing the value of the quantity c, I have used the mean values of the coefficient n, making it variable with the velocity, according to the law established by Hutton.

The results of the calculations, and their comparison with those of the experiments, are exhibited in the following table :

|                  | POW               | DER.              | llad                                         | co             | -0 RDIN                          | TES OF                           | THE TR                        | AJECTO                           | RY.              |

# 294 COMPARISON OF THE EXPERIMENTAL WITH THE

### COMPUTED RANGES OF CANNON BALLS.

The close agreement here found between the results of calculation and those of experiment must be regarded as a confirmation of Hutton's conclusions respecting the law of resistance of the air to balls moving with great velocities; or, at least, it shows that this law is applicable to practice within the limits of elevation and distance in which the above form of the equation of the trajectory can be applied, including most of the cases of ricochet firing.

The greater disparity between the experimental and computed ordinates of the trajectory, in the practice with the powder W, in the 24-pounder gun, may be attributed to a want of precision in leveling the bore of the gun, which, in that case, was mounted on a barbette carriage. It will be seen that a much nearer coincidence in the results is produced by making the correction for the term  $x \tan g$ .  $\blacklozenge$ , computing the angle of departure by Lombard's method. A similar coincidence of the experimental and theoretic ordinates is found in the last round of these experiments, where the ball passed (as will be seen in the Journal) through the centre of the target, at 50 feet from the gun; thus showing that it must have left the piece very nearly in a horizontal direction.

•

## SUMMARY OF THE EXPERIMENTS

# VI. SUMMARY OF THE EXPERIMENTS WITH THE MUSKET PENDULUM.

### REMARKS ON THE EXPERIMENTS

### REMARKS.

# 1. Influence of the density and size of grain on the force of powder for small arms.

From the foregoing table, we find that in the musket, as in other arms in which small charges are used, the highest velocities are produced, generally, by powder of low density, if the grains be large, and by the finest grain of dense powders. The influence of the size of grain on the force of dense powder is strikingly shown by a comparison of the velocities given by powders A.1 and A.4, G.1 and G.6, which differ in scarcely any thing but the size of grain. On the other hand, by comparing the velocities given by the different sizes of grain of powder F, we see that very little effect on its force is produced by variations in the size of grain, if the powder is of low density. It is remarkable indeed that, in this case, the large grain may give the ball a greater velocity than the small grain; thus the French cannon powder, (which resembles the sample F,) gives a greater velocity than the musket powder, which differs from it only in the size of grain; and the same circumstance is remarked in the proof of these samples by the musket pendulum in France, as inscribed on the original packages.

The influence of the density of grain on the force of powder, in the musket charge, is strikingly exemplified by comparing the several samples of powder R, from which it appears that the advantage of the more thorough incorporation, produced by additional working, is more than counterbalanced, in large grained powder, by the increase of density, which diminishes the quickness of burning.

Although our best musket and rifle powders, A. 4 and A. 5, leave little to desire in point of strength, the proper proportion between the density and size of grain, in the musket powder

### WITH THE MUSKET PENDULUM.

t least, appears to be better observed in the English powders,
which are finer grained than ours. There will be an advantage, independently of the increase of force, in reducing the size of grain of musket powder for use in percussion arms, as that will cause the powder to enter more readily into the cone, and thus increase the certainty of ignition.

In accordance with this view, the powders X. p. 4 and X. p. 5 were prepared; but having been made of the dust of cannon powder re-worked, and again pressed, the density of the powder is rather too great for the musket grain, which was also in this case too much equalized in size to produce the greatest effect.

# 2. Effect of wads in small arms.

We have before seen that no appreciable increase in the inherent force of the charge in a heavy gun is produced by the use of wads; but the numerous experiments on the different modes of wadding the musket, show that, in small arms, the wad has a very great influence on the development of the force of the charge. By increasing the resistance to the motion of the ball, the wad causes the perfect combustion of the powder to take place in a smaller compass than it would otherwise do, and the intensity of the force is thus increased in a greater ratio than the resistance.

It is satisfactory to find that the most advantageous wad is the paper of the musket cartridge, as it is used in ordinary service.

The effect of increasing the resistance to the motion of the ball, and diminishing the space occupied by the charge, is shown by the experiment on the 13th December, where, by repeated ramming, the height of the charge in the barrel was reduced from about 1.9 in. to 1.6 in., and the velocity increased more than 100 feet, or  $_{15}^{15}$ th part.

38

### REMARKS ON THE EXPERIMENTS

## 3. Influence of a diminution of windage.

This subject is akin to the preceding, as the effect of the wad is no doubt due, in a great measure, to its tendency to reduce the windage and lessen the escape of the inflamed fluid.

The influence of this cause is, however, more clearly exemplified by comparing the velocities impressed, by different charges of powder A. 4, on balls of different windage. From this it appears that a reduction of 0.01 in. in the windage is nearly equivalent in effect to an increase of 10 grs. in the charge, notwithstanding the increased weight of the larger That this result was not obtained in the experiments ball. with the powder X. p. 4 is attributable to the fact that, in this case, the balls although stated to be of 0.04 in. windage, were sensibly smaller than those of a similar kind used with the powder A. 4.; so that the difference of windage was only sufficient to compensate for the difference of weight, by giving to the heavier ball nearly the same velocity as to the lighter. But the influence of the diminution of windage, on the force of a charge of this powder, appears by comparing the velocities obtained in the experiments of December 13th and 19th, 1844, with the same charge of powder and ball, in muskets of different sized bores, as exhibited in the table under the succeeding head.

# 4. Effect of using percussion primers.

The following is a summary of the comparative experiments made by firing, a musket, alternately, with quick match and with percussion primers :

| June 5                            | 5             | G. 6           | 120                     | 0.05                         | 397.5                       | 1864                           | 1888                          |                                              |

These experiments appear to me sufficient to show that, although the increase of force by the use of the percussion primer, which nearly closes the vent, is constant and appreciable in amount, yet it is not of sufficient value to authorize a reduction of the charge on this account alone. They are, therefore, far from confirming the conclusions drawn by Mr. Lovell, of the Royal Manufactory of arms at Enfield, England, from his experiments, as stated in Ure's Dictionary, (art. Fulminate,) viz: that 8.84 parts of gunpowder fired with percussion are equal to 10 parts fired with flint.

I am not acquainted with the construction of the "recoiling target" used by Mr. Lovell, nor with the other details of his experiments; but we have seen, in the present course of experiments, that great irregularities may be produced in the force of the musket charge by slight variations in the windage of the ball, or in the manner of loading and ramming the charge, and that great care is, therefore, requisite to confine these variations within narrow limits, in order to estimate accurately the change which is due to any other special cause of variation.

### OF THE PROPER CHARGE

### 5. Of the proper charge for the percussion musket.

The cartridge for the flint musket contains 130 grains weight of powder, from which, deducting about 10 grs. for priming, we have 120 grs. for the charge which is put into the musket. This charge has always been considered ample in service, and when composed of the best powder, it is quite as much as can be used with comfort to the soldier, in firing the present ball of 18 to the pound.

The sufficiency of this charge may also be deduced, by analogy, from that of the French flint lock musket, which is the model of ours. When the charge was established at the present standard of 146.5 grs., it was found, by numerous experiments, that the effect of this charge, with the ball of 1S to the pound, was equal to that of the former charge of 189 grs., with the old powder, and the ball of 19 to the pound; and this latter charge, having been used in all the wars of the Revolution, was thought to have been proved sufficient, by long experience. Now, by the experiments with powders from a large number of the French powder works, which led to the adoption of the present standard of proof by means of the musket pendulum, it was found that the mean velocity of the ball, with a charge of 154 grs., (10 grammes,) was 1477 feet, which was therefore adopted as the minimum velocity for the proof of musket powder. The proportional velocity with a charge of 146.5 grs., would be 1440 ft., considerably below that of 1500 ft., which we have obtained for the same ball, with the charge of 120 grs. of the powder A. 4. It may be remarked, here, that some of the French musket powder, although made in the pounding mill, is of not very inferior force to this powder A. 4, as will be seen by the experiments with the sample of powder made at Bouchet, which gives a velocity of 1478 ft. with a charge of 120 grs., and would there-

### FOR THE PERCUSSION MUSKET.

fore give about 1630 ft. with the charge of 146.5 grs. But we see that, by reducing the size of grain of our musket powder and making it conform more nearly to the English powder, we may obtain, with a charge of 120 grs., a force nearly equal to that of this Bouchet powder, with a charge of 146.5 grs. We may, therefore, regard this charge of 120 grs. as sufficient for the musket, with a ball of 18 to the pound, having 0.05 in. windage.

But we find, from the table of experiments, that by reducing the windage of the ball to 0.04 in., and increasing its weight to  $\frac{1}{17}$ th of a pound, we may obtain, with the percussion musket, as great a velocity for this heavier ball with a charge of 110 grs., as for the smaller and lighter ball with 120 grs., and this without any increase of the force of recoil. Having satisfied myself, by the trials mentioned in the Journal, that this increase in the diameter of the ball will not impede the service of the arm, if the balls are smooth, I propose that the changes above indicated, in the kind of powder, the charge and the size of the ball, should be adopted in service, and that in order to ensure the uniformity and smoothness of the balls, they should be made by compression, as is now practised in the British service, and in some others.

In this manner we may obtain, with the charge of 110 grs., in the percussion musket, an initial velocity of about 1550 ft., which is greater than requisite for a musket ball, and leaves sufficient room to allow for deterioration of the powder, or for accidental loss of a small portion in loading, &c., as well as for variations of windage, consequent on the differences permitted in the bores of muskets.

As a further evidence of the sufficiency of this charge, we may compare the experiments on the range of the musket, (or the ordinates of the trajectory, at different distances from the muzzle,) with those made in France, with the same ball of 17

### 304 CHARGE FOR THE PERCUSSION MUSKET.

| FRENCH<br>Charge      |                      | 1                | X. p. 4;<br>110 grs. |
|-----------------------|----------------------|------------------|----------------------|
| Abscissa.             | Ordinate.            | Abscissa.        | Ordinate.            |
| Yds.                  | In.                  | Yds.             | In.                  |
| 76.6<br>120.3<br>153. | 6.38<br>17.<br>28.83 | 80<br>120<br>150 | 7.7<br>23.<br>32.    |

to 1 lb., and the old charge of 189 grs., as stated in the Aide Mémoire d'Artillerie :

According to the same authority, an elevation of 33 min. is required for a range of 219 yds. with the charge of 146.5 grs. and the ball of  $_{18}^{-1}$ th lb.; and I find nearly the same result with the ball of  $_{17}^{-1}$ th lb. and the charge of 110 grs., viz: that an elevation of about 36 min. is required for a range of 200 yds. The range of 500 yds. requires, with this charge, an elevation of less than  $3\frac{1}{2}^{\circ}$ , and at that distance the ball retains sufficient force to pass through a pine board 1 in. thick, showing that it would inflict a serious wound at a still greater distance.

I may add, also, that the charge for the British percussion musket is reduced to  $4\frac{1}{2}$  drachms, or 123 grs., whilst the ball is  $14\frac{1}{2}$  to the pound, or 480 grs. This charge is therefore smaller, in proportion to the weight of the ball, than that here proposed, in the ratio of 3.73 to 3.93.

By the new edition of the Aide Mémorie d'Artillerie, I find that a change similar to that which I propose has been adopted in establishing the charge of powder and ball for the new percussion musket in the French service. The windage of the ball has been reduced to 0.04 in.; and although the bore of the musket is enlarged, so as to receive a ball of  $_{T5}$ th lb., or

#### COMPARISON OF VARIOUS SMALL ARMS.

Sears almost exactly the same proportion to the weight of the ball as that which I propose; but the use of pounding mill powder is continued for the military service in France, not-withstanding its inferior force in most cases.

### 6. Comparison of the force of the charge in various arms.

### SUMMARY OF THE EXPERIMENTS MADE WITH DIFFERENT SMALL ARMS, OF RIFLE CALIBRE.

\* Loading at the breech.

For the description of these arms, and for other particulars of the experiments, reference is made to the Journal.

The great accession of force obtained by *slugging* the ball is shown by the experiment with Jenks's carbine, in which nearly the whole force of the charge is exerted on the ball, giving it a velocity equal to that of the ball from the Cadet's musket, notwithstanding the great difference in the length of bore of the two arms.

In Hall's arms, the loss of force, by the opening between the chamber and the barrel, is more than sufficient to neutralize the

### COMPARISON OF VARIOUS SMALL ARMS.

advantage of destroying the windage of the ball; so that a given charge impresses on the ball from Hall's rifle, a much smaller velocity than from the common rifle loaded with a patched ball.

The force of the charge of 35 grs. in the pistol, is greater than necessary for that arm, and the experiments made on the 19th Dec'r, 1844, show, that with 30 grains of good powder, the pistol ball is propelled with sufficient velocity to inflict a severe wound even at more than 80 yards; but as this charge can be fired without inconvenience to the hand, I should not propose less than 30 grs. as the charge for the pistol.

Numerous experiments on ranges, made at Washington Arsenal, have shown, that with good powder, the charge of 70 grs. is sufficient for the percussion rifle, even at the distance of 300 to 350 yards, and we might draw the same inference from the velocity which this charge communicates to the ball; but as the charge of 75 grs. can be fired with perfect ease, and without *stripping* the ball, it would be perhaps safer to adopt that charge, in order to provide for accidental loss, deterioration of powder, &c. This charge is considerably greater, in proportion to the weight of the ball, than those lately adopted for the English and French service rifles; but it is properly so, because the ball of our rifle, being of less than half the weight of either of those, will be more affected by the resistance of the air, and should, therefore, have a greater initial velocity.

In order that Hall's rifle may be effective at long distances, its charge should hardly be less than 100 grs., and the chamber of the rifle ought to be enlarged, to admit that charge, if the arm should be again put in service.

Charge of powder 12 oz.; weight of ball 48 lbs.

The ranges and relative force of powders tried by this mortar, with the above mentioned charge, follow nearly the order of the quickness of inflammation of the several kinds of powder, and the inverse order of their densities, whatever may be the mode of manufacture, or the degree of incorporation of the components of the powder; thus showing, that the qualities required for developing the greatest force of powder, in very short pieces of ordnance, are materially different from those requisite for the same purpose in long guns. But the high rank occupied in this respect by the powder H, in practice both with the gun and with the mortar, proves that it is not impossible to combine these qualities in such a manner as to produce gunpowder which shall be well adapted for the service of long guns, and still possess a considerable force in the mortar.

Charge 2 oz. of powder, without ball or wad.

#### WITH THE EPROUVETTES."

# Remarks on the proof of powder by the eprouvettes.

By comparing the results of the proofs by the eprouvettes with those furnished by the cannon pendulum, it will appear That the eprouvettes are entirely useless as instruments for testing the relative projectile force of different kinds of powder, when employed in large charges in a cannon. Powders of little density or of fine grain, which burn most rapidly, give the highest proof with the eprouvettes, whilst the reverse is nearly true with the cannon. Thus all the eprouvettes concur in assigning the first rank among the cannon powders to the powder F, which is the lowest on the scale by the cannon; whilst the powder A, which is the strongest in the gun, is one of the weakest by the eprouvettes. Nor do these instruments assign any superiority to powder, which is well incorporated, over powder of the same kind, in other respects, which has been very imperfectly worked; on the contrary, they all give results with the powder incorporated by 15 minutes work under the rollers, equal or superior to those furnished by the same powder worked 90 minutes.

The only real use of these eprouvettes is to check and verify the uniformity of a current manufacture of powder, where a certain course of operations is intended to be regularly pursued, and where the strength, tested by means of any instrument, should therefore be uniform; but as a means of proving gunpowder received, as it is in our service, from manufactories pursuing entirely different processes, these eprouvettes may be pronounced worse than useless, since they may lead to erroneous results. By the French mortar eprouvette, scarcely any of the powders which we have found to be the strongest in the cannon, could be received as having given the required proof range of 246 yards.

The results by these eprouvettes correspond generally with

### 312 SUMMARY OF THE EXPERIMENTS

those given by the 8 in. mortar, with a charge of 12 oz., by the 1-pounder gun pendulum, and by the musket pendulum, in which, as in all cases where small quantities of powder are used, rapidity of inflammation is the most influential element of strength.

Comparison of the observed time of flight of a ball from a mortar, with the time computed by regarding the trajectory as a parabola.

|                                                                             |                       | No. of<br>rounds.                    | Mean                                           | Initial                                       | TIME OF FLIGHT.                            |                                       |                                      |                                             |  |  |

In estimating the relative force of the powders, as indicated by these mortars, the trajectory is regarded as a parabola, and the velocity is, therefore, supposed to be proportional to the square root of the range.

#### XI. EXPERIMENTS WITH THE 1-POUNDER GUN PENDULUM.

Having ascertained that there is no correspondence between the indications of the force of cannon powder, which are furnished by the gun itself, and those given by the eprouvettes in common use, and also that no accurate indication of the relative force of different kinds of powder can be expected from the use of blank charges, even with large quantities of powder, I determined to try whether such an indication would be

#### with the 1-pounder gun pendulum.

**furnished** by firing with balls from a gun of so small a calibre that its use would be attended with little difficulty or expense, and that the apparatus might even be susceptible of removal, if necessary, from place to place. For this purpose, I constructed a pendulum apparatus for a 1-pounder gun, to be fired with balls, with a charge of  $\frac{1}{4}$  lb.; the velocity of the ball to be computed from the recoil of the gun pendulum alone, in order to dispense with the costly and slow process of using the ballistic pendulum.

The results of the experiments with this pendulum are exhibited in the following table :

Summary of experiments with 1-pounder gun pendulum. Charge of powder  $\frac{1}{4}$  lb.; windage of ball 0.0475 in.

| Kind                                                                                                   | Initial                                                                                                               | Relative                                                                                              | Kind                                                                                                            | Initial                                                                                               | Relative                                                                          |  |

From these results, it appears that the indications given by the 1-pounder gun, with respect to the relative force of different kinds of powder, conform much more nearly to those of the eprouvettes and the musket, in which small charges are

#### 314 EXPERIMENTS WITH 1-POUNDER GUN PENDULUM.

used, than to those of the cannon with large charges. Thus\_ again, the powder F, which is among the weakest of the cannon powders in the 24-pounder gun, occupies nearly the highest rank in the 1-pounder gun; and the powder A, which is the strongest of all the cannon powders in the former gun, stands almost at the foot of the list in point of strength when tried by the latter; a similar remark may be made with respect to the powders D and K. In short, it appears that low density and fineness of grain, which are the qualities most favorable to the quickness of powder, exercise, in general, the greatest influence on the force of small charges; whilst in large charges, (unless the powder is excessively dense, as the sample E,) the slower development of force, which would be caused by the less rapid combustion of the coarse grains of dense powder, seems to be more than compensated by the greater intensity of the flame produced by such powder. So that, in the combustion of large charges, the whole force of the powder is actually developed in a smaller compass, and therefore with greater effect, when the powder is dense.

This remark may be illustrated by a comparison of the initial velocities of balls fired with similar charges from a large and a small gun, of nearly the same relative length of bore. Thus, with a charge of  $\frac{1}{4}$ th the weight of the ball, we have :

# With powder A.

| In the 24-pounder gun, a velocity of | - | 1702 feet. |

.

#### GENERAL CONCLUSIONS.

#### XIII. CONCLUSIONS.

The following are some of the practical conclusions which have been suggested to me by the results of these experiments.

# 1. With regard to the proof of gunpowder.

The only reliable mode of proving the strength of gunpowder is to test it, with service charges, in the arms for which it is designed; for which purpose the ballistic pendulums are perfectly adapted.

Although the present tendency to the use of cannon of very large calibre would make the proof by means of a 32-pounder or 24-pounder gun more satisfactory than by using a piece of smaller calibre, it does not seem to be necessary to resort to those heavy guns for obtaining a correct indication of the relative force of different kinds of powder. We have seen, indeed, that such an indication is not given by a 1-pounder gun; but the experiments at Metz have shown that the 12-pounder gun classes the powders in the same order of strength as the 24pounder, and further experiments may, perhaps, prove that a long gun of yet smaller calibre, a 9-pounder or a 6-pounder, will give corresponding results. As the use of the large ballistic pendulum is difficult, slow, and expensive, and as the indications furnished by the recoil of the cannon pendulum correspond with those given by the ballistic pendulum, I should propose, for the usual proof of gunpowder, to make use of the cannon pendulum alone; employing a gun of the smallest calibre which will give correct results, and firing the balls into a bank of earth, which would not make them unfit for ordinary service.

An apparatus of this kind would not be costly, and might, therefore, be erected at several of the Arsenals, where powder

may be conveniently received for inspection; the 24-pounder pendulum at Washington Arsenal being used occasionally, for verification.

In the 24-pounder gun, new cannon powder should give, with a charge of  $\frac{1}{4}$ th, an initial velocity of not less than 1600 feet, to a ball of medium weight and windage.

For the proof of powder for small arms, the small ballistic pendulum is a simple, convenient, and accurate instrument. The cost of the apparatus might be very much reduced, without impairing the accuracy of the results, by dispensing, in most cases, with the musket pendulum, which is the most costly part of it, and simply firing the ball into the ballistic pendulum block, from a barrel set in a permanent frame.

The initial velocity of the musket ball, of 0.05 in. windage, with a charge of 120 grains, should be:

With new musket powder, not less than 1500 feet;

With new rifle powder, not less than 1600 feet;

With fine sporting powder, not less than 1800 feet.

The common eprouvettes are of no value as instruments for determining the relative force of different kinds of gunpowder.

## 2. Of the hygrometric test of gunpowder.

Although the projectile force of gunpowder is the most important quality to be attended to in the proof and inspection, its capability of being long preserved without much deterioration, and of resisting the effects of such exposure as it is subject to in service, must be regarded as of little less importance. This quality should, therefore, be tested either by comparing the quantity of moisture absorbed, under similar circumstances, by the powder which may be under trial, and by other powder of approved good quality; or by the application of a simple chemical test of the purity of the saltpetre, as it is on

this circumstance chiefly that the capacity of the powder toresist the action of a moderate degree of moisture depends.

#### 3. Of the proportions of the ingredients of gunpowder.

The proportions used in making our best powder, 76—14— 10, and the English proportions, 75—15—10, appear to best favorable to the strength of powder, and not sensibly disadvantageous in other respects; but the ordinary variations in the proportions of cannon powder are scarcely appreciable by their effects on its force.

# 4. Of the mode of manufacture.

The powder of greatest force, whether for cannon or small arms, is produced by incorporation in the "cylinder mills," under heavy rollers, and this process alone is now considered capable of making sporting powder of the best quality. This is the mode of incorporation which has been practised for more than 50 years in England, and the superior quality universally attributed to the English powders is attested by the results of my experiments with them. I would, therefore, propose the Waltham powder as the type or standard to which our powder for military service should conform in nearly all respects. In this manufacture, the essential operations are the separate pulverization of the materials, their incorporation by the cylinder mills alone, and the formation into cake by moderate pressure, on thick cakes. The time of running the mills on a given charge must depend partly on the weight of the rollers; but the diminution of this time by means of previous mixture of the ingredients for several hours, in the dust barrels, appears to impart to the powder a degree of density which, although attended, perhaps, with somewhat increased force in the cannon, is injurious to other valuable

qualities of the powder, and especially to its capability of resisting the effects of exposure to moisture.

I have mentioned in this Report, the well-known fact that, after all the experiments with gunpowder in France, the use of the pounding mill is still continued in making all powder for the military service. This decision results principally from three advantages claimed for the pounding mill powder over that made by other processes : 1st, that it is better adapted to the promiscuous service of all arms; 2d, that it is less injured by exposure to moisture; 3d, that it is less destructive to the gun. The first of these advantages has no value in our service, because we shall, undoubtedly, continue to use, as we have always done, different kinds of powder for cannon and for small arms. As for mortar service, we have seen that the rolling mill powder, if not made of undue density, is but little inferior to the other, even with small charges. In mortars, also, we have always the faculty of varying the charge and elevation according to the range required, and the use of mortars will probably be so much diminished by the introduction of long howitzers of all calibres, that no sacrifice of the strength of powder in long guns should be made for the sake of adapting it to mortar service.

With regard to the second advantage claimed for pounding mill powder, we see that it may also be possessed in a high degree by rolling mill powder, such as the English Government powder.

The French experiments themselves indicate a simple method of neutralizing, in a great degree, the destructive quality of dense powder without diminishing its projectile effect, and this may be still further accomplished by the reduction which the greater force of the latter kind of powder enables us to make in the charge.

The strength of the barrels of small arms is so great that 41

the destructive effect of the small charges used in them constitutes no objection to the use of powder even more violent in its operation than the strongest rifle powder proposed to be made.

I have before said that the pounding mill is capable of producing powder of nearly equal force to the cylinder mill powder, but for that purpose it must be worked not less than 14 or 16 hours, and even then, unless it is pressed, the grain is hardly sufficiently firm to bear, without injury, the jolting of ammunition wagons.

# 5. Of the density of gunpowder.

Here, again, I propose to refer to the English standard, according to which the mean gravimetric density of the coarse grains of cannon powder is about 875. That density should not be *less* than 850; it is not easy, and perhaps not necessary, to establish an absolute *maximum* of density, on account of the differences caused by accidental variations in the size and form of the grains; but it does not appear necessary or advisable that the gravimetric density should exceed 920.

# 6. Of the sizes of grain for gunpowder.

For cannon powder, no change appears to be required in the present regulation with respect to the size of grain.

If it should not be deemed incompatible with the convenience of service to multiply the varieties of powder for special purposes, there would probably be an advantage in using very large grained powder, (such as that designated by A. 0,) for 13 in. mortars and for the heavy sea coast howitzers, in which enormous charges of powder are used. By this means the strain on the gun would be diminished, and the velocity of the ball perhaps increased; and we have seen that, even in the 32 and 24-pounder guns, with moderate charges,

the velocity of the ball is not diminished, in an important degree, by the use of such powder.

For musket powder, I would recommend a reduction of the size of grain, to be regulated by the present standard gauges as follows:

All the grains should pass through No. 4.

About one-half, through No. 5.

Nearly one-fourth, through No. 6.

This would give about 2000 or 2500 grains of powder in 10 grs. troy.

For *rifle powder*, a small reduction may also be made in the size of grain, by requiring that all the grains shall pass through No. 6, the other gauges being used according to the present regulation. There would then be about 12,000 or 15,000 grains of powder in 10 grs. troy.

# 7. Of the charges for cannon and small arms.

For cannon, the charge of  $\frac{1}{4}$ th the weight of the ball, with powder of the standard strength proposed, impresses on the ball a sufficient velocity for all the ordinary purposes of service. For any purpose, even for a breaching battery, the advantage gained by using a charge greater than  $\frac{1}{3}$ d the weight of the ball is unimportant, and by no means compensates for the inconvenient recoil, and the destructive strain on the gun and carriage, &c.

In illustration of these conclusions, it might suffice to refer to the tables of experiments; but as the habitual charge in the French and other services is  $\frac{1}{3}$ , and the battering charge  $\frac{1}{2}$  the weight of the ball, it may be well to compare the effects of these charges of French powder with that of the charges which I propose to substitute for them. For this comparison, a glance at the following table will suffice.

The French 30-pounder corresponds, very nearly, in diame-

ter and length of bore, with our 32-pounder. The windage of the balls used in the French experiments is somewhat greater than that of the balls used in my experiments, but the difference is not very important.

For small arms, the following charges are proposed :

For the percussion musket, with the proposed musket powder, 110 grains.

For the percussion rifle, 75 grs.

For the percussion pistol, 30 grs. of rifle powder.

8. Of cartridges for cannon.

For the purpose of diminishing the strain on the gun, I propose that the principle of increasing the length of the cartridge, by reducing its diameter, should be adopted for heavy guns. The diameters of the cartridge formers may be established as follows:

| Calibre                      | -        | 42 | 32  | 24 | 18  |
|------------------------------|----------|----|-----|----|-----|
| Diameter of cartridge former | - Inches | 6. | 5.5 | 5. | 4.6 |

### 9. Of the windage of balls for cannon and small arms.

In view of the great diminution of velocity, which may be caused even by such a difference of windage as may occur from the variations now allowed in the diameter of the bore and that of the ball, I recommend that the limits of those variations should be restricted. In the present state of the mechanic arts, the manufacturers can, without difficulty, execute their work with greater uniformity than is required by the existing regulations on this subject; and I believe that, in fact, the limits of variation allowed are seldom reached. It is therefore only necessary to make obligatory on all, the present practice of the best workmen.

With regard to cannon balls, I have found no difficulty in restricting the variations of diameter to *one-half* of what is now allowed, and although I should not propose to confine the founders to this narrow limit, yet I think it would be useful to require that a certain proportion of the balls should come between the high gauge and an intermediate gauge between the high and low gauge; this would cause the moulders to work as nearly as possible to the high gauge.

For small arms also, especially for the musket, the variation now allowed in the diameter of the bore is, I believe, unnecessarily great. But for these arms, a much more important change is that of reducing the windage, by increasing the diameter of the ball, and to effect this object, with certainty and uniformity, I propose that balls for small arms shall be made by compression, instead of being cast.

### 10. Of the loss of force by the vent of the gun.

The loss of velocity in consequence of the escape of gas through the vent of a cannon is inappreciable, in comparison with the unavoidable variations produced by other causes, and,

### conclusions.

so far as this effect is concerned, it would be nearly useless termination to be a series to be a series of the se

# 11. Of the effect of wads.

In the service of *cannon*, heavy wads over the ball are, in all respects, injurious. For the purpose of retaining the ball in its place, light *grommets* should be substituted for junk or hay wads, and the latter should be used only for proving guns, forfiring hot shot, or for saving the bore of the gun from injuryby placing them between the powder and ball, in order to change the seat of the ball, from time to time, and prevent the formation of a *lodgement*.

In *small arms*, on the other hand, it is of great importance, for developing the full force of the charge, that there should be a good wad over the powder, unless the ball has but very little windage, as in the rifle.

12. The great differences observed in the strength and solidity of cannon balls, made at different foundries, indicate the propriety of greater care, in the manufacture and proof of balls, than is now bestowed on them.

13. The stock of powder in store, of the kinds designated by the letters C and D, in this Report, should be used in current service before the other kinds.

> A. MORDECAI, Capt. Ordn. Dept.

WASHINGTON ARSENAL, February 11th, 1845.
